Abstract
Potential precursors have been prepared for intramolecular 1,3-dipolar cycloaddition to form a
pyrrolo[3,4-b]isoxazole. The cycloaddition has not to date been accomplished, however an
unexpected retro-Claisen reaction is reported.

Keywords: Acetoacetylation, nitro amine, aza-Henry reaction, retro-Claisen reaction, urea

Introduction

We have reported over a number of years on synthetic approaches to the 3-acyltetramic acid
group of metabolites, which display an N-heterocyclic enolised tricarbonyl core, as illustrated in
general structure 1 (Figure 1).1 These metabolites show a range of biological activities, ranging
through antibiotic, antitumour, antifungal and antiviral2; they also have a relationship to the
inducers of bacterial quorum sensing.3 Over recent years we have focussed on pyrroloisoxazoles
2 and 3 as providing masked forms of the polar enol functionality in the acyltetramic acids.4-6

Figure 1. General structure of 3-acyltetramic acids 1, and pyrroloisoxazole masked forms 2 & 3.

Most recently we have reported on our 2nd generation approach that employs the 5,6-
dihydropyrrolo[3,4-b]isoxazol-4-one building block 2 through the route shown in Scheme 1,
which involves the 1,3-dipolar cycloaddition of an amino acid-derived nitrile oxide dipole with a
β-ketoester enamine as dipolarophile.5 One of the less efficient steps in this sequence is the ring
closure (lactam formation) of 3-(1-aminoalkyl)-5-methylisoxazole-4-carboxylates to complete
the pyrroloisoxazole framework 2. We were interested to investigate whether this sequence could be improved by reversing the order of N1-C2 bond formation and cycloaddition, making the amide bond first, which would also have the possible benefit of making the cycloaddition intramolecular. We report here our efforts to date, which generated an intermediate having a nitro group as dipole precursor and a β-keto amide as dipolarophile precursor, but revealed an unexpected retro-Claisen reaction on attempting to generate the dipolarophile.

Results and Discussion

Authors, please provide missing symbols

As the desired dipolarophile in the cycloaddition is an enamine prepared from a β-keto acid derivative, an obvious initial approach based on intermediates we had in hand was N-acetoacetylation of an amino acid-derived oxime. The nitrile oxide dipole would be prepared from the aldoxime via C-chlorination and 1,3-dehydrochlorination. Using valine as our test amino acid scaffold, the aldoxime 4a was prepared from N-tert-butylxycarbonyl-5-valine methyl ester (DIBAL-H, toluene, –78 °C, 2 h; then NH₂OH.HCl, NaOAc, EtOH aq, 70 °C, 10 min) in 89% yield as a 2:1 mixture of geometric isomers (Scheme 2). Acetoacetylation was attempted using 2,2,6-trimethyl-1,3-dioxin-4-one, the diketene-acetone adduct (PPTS, toluene reflux, 3 h).⁷ The results were inconsistent, with product ¹H NMR spectra sometimes showing loss of the tert-butyloxycarbonyl group and sometimes not. Samples retaining the tert-butyloxycarbonyl group had ¹H NMR spectra that implied acylation of the oxime N-atom rather than the amine function, with a signal for the proton NHBoc being observed at δ 4.62 (1H, d, J 9.6 Hz). More surprisingly, the NMR spectra suggested the reduced structure 5a, having an unexpected additional CH₂N signal (δ 4.11-4.24, 2H, m; δC 65.6) and no oxime sp²-CHN
signals, although we were unable to fully characterise this material. A test with FeCl₃ supported
the assignment of a hydroxamate structure. The capricious behaviour in the thermolysis led us
to switch to the corresponding N-benzylloxycarbonyl aldoxime 4b, prepared from N-
benzylloxycarbonyl-S-valine methyl ester as outlined above for the tert-butyloxycarbonyl
compound 4a. Thermolysis with the diketene-acetone adduct, however, again gave a product
assigned as the hydroxamate 5b, showing δ 3.62-3.68 (1H, m, CHNHZ), 4.07-4.17 (2H, m,
CHCH₂N), 4.62 (1H, d, J 9.6 Hz, CHNHZ), δ 67.0 (CH₂N), and no oxime CH signal. Again,
full characterisation could not be accomplished. A redox process is clearly implicated alongside
these acylations, but we are unable to identify the reducing agent. Changing the acetoacetylation
agent to the more reactive diketene but omitting the acid (toluene reflux, 3 h) led to the same
presumed hydroxamates 5a,b from the aldoximes 4a,b, respectively.

Scheme 2. Attempted acetoacetylation of α-amino oximes. Reagents: i, DIBAL-H, toluene, –78
°C; ii, NH₂OH.HCl, NaOAc, EtOH aq., 70 °C; iii, 2,2,6-trimethyl-1,3-dioxen-4-one, pyrH⁺OTs,
toluene reflux; or diketene, toluene reflux.

These results led us to avoid the oxime as a precursor functional group for the nitrile oxide
dipole. Instead we targeted the dehydration of a primary nitro group as the route to the nitrile
oxide. Our target thus became an N-protected S-2-methyl-1-nitromethyl-1-propanamine 6a or 6b
(Scheme 3), which could be N-acetoacetylated. Thus S-valinol 7 (prepared by reduction of S-
valine: TMSCl, NaBH₄, THF, 0 °C, 24 h; 78%) was selected as starting material. A good
leaving group was now needed at the alcohol function for substitution to generate a primary nitro
group, but attempted toluene-4-sulfonylation (TsCl, DCM, 0→20 °C, 17 h) unsurprisingly
afforded the N-sulfonylated compound 8 (100%) rather than the desired O-sulfonylated
compound. Thus S-valinol 7 was N-protected as the tert-butyloxycarbonyl derivative 9a (Boc₂O,
Et₃N, DCM, 0→20 °C, 17 h; 100%) and benzylloxycarbonyl derivative 9b (PhCH₂OCOCl,
NaHCO₃, EtOAc-H₂O, 0→20 °C, 17 h; 90%). The corresponding mesylate derivatives 10a and
10b were formed by a standard method (methanesulfonyl chloride, Et₃N, DCM, 0→20 °C, 4 h)
in crude yields of over 90%. Attempts to use these crude materials in a nucleophilic substitution
with nitrite were unsuccessful (NaNO₂, toluene or DMF, 0→60 °C, 17 h) with the alcohols 9a
and 9b being recovered after aqueous workup. The mesylates were instead treated under
Finkelstein conditions (NaI, acetone reflux, 17 h) in an attempt to generate the corresponding
iodo compounds 11a and 11b, respectively. The N-tert-butyloxycarbonyl derivative 10a
however, underwent protecting group cleavage to afford the cyclic carbamate 12; the N-benzyloxycarbonyl compound 10b did give the iodo compound 11b (42%) along with some cyclic carbamate 12 (7%). It is assumed that anchimeric assistance by the N-protecting group carbonyl oxygen atom is followed by loss of a carbenium ion (to afford the cyclic carbamate) competing with iodide nucleophilic attack. In an alternative direct iodination from alcohol 9a, iodontriphenylphosphonium iodide was prepared (triphenylphosphine, iodine, DCM) to which imidazole and alcohol 9a was added and the mixture heated under reflux for 17 h to afford the iodide 11a (31% after chromatography). The yield and product purification was improved by replacing the triphenylphosphine with a polymer-supported triphenylphosphine, to afford the iodides 11a (43%) and 11b (80%) from the corresponding alcohols 9a and 9b, respectively. Traces of the cyclised by-product 12 were sometimes observed in these reactions. The nitro substitution was undertaken with the iodo compounds, now using sodium nitrite in DMF (20 °C, 20 h) with the addition of phloroglucinol and urea to minimize the formation of nitrite ester. The corresponding N-tert-butyloxycarbonyl and N-benzyloxycarbonyl S-2-methyl-1-nitromethylpropanamines 6a (64%) and 6b (70%) were isolated along with small recoveries of the corresponding alcohols 9a or 9b.

Scheme 3. Preparation of protected S-2-methyl-1-nitromethylpropanamines 6. Reagents: i, TsCl, DCM, 0–20 °C; ii, For 9a: Boc₂O, Et₃N, DCM, 0–20 °C. For 9b: PhCH₂OCOCI, NaHCO₃, EtOAc-H₂O, 0–20 °C; iii, MsCl, Et₃N, DCM, 0–20 °C; iv, NaI, acetone reflux; v, PS-PPh₃, I₂; then imidazole; vi, NaNO₂, DMF, phloroglucinol, urea, 20 °C.

This route to optically active N-protected S-2-methyl-1-nitromethylpropanamines was complemented by a reported approach to the N-tert-butyloxycarbonyl R-compound 6c via the aza-Henry reaction (Scheme 4). Thus, sodium benzenesulfinate in water was added to tert-butyl carbamate (THF, 20 °C), followed by 2-methylpropanal and methanoic acid. After 17 h, the white precipitate was recrystallized to afford the sulfone 13 (75%). Reaction with nitromethane in the presence of potassium hydroxide (toluene, –78–20 °C, 48 h) and catalytic
benzylquininium chloride led to the nitro compound 6a (72%). Replacing potassium by cesium hydroxide led to incomplete reaction after 48 h, in contrast to one of the earlier reports. The nitro compound prepared by this route was formed highly stereoselectively, whereas the route from S-valine was stereospecific.

**Scheme 4.** Alternative preparation of R-nitromethylpropanamine 6a. *Reagents:* i, BocNH₂, PhSO₂Na, THF aq., 20 °C; ii, MeNO₂, KOH, benzylquininium chloride (12 mol %), toluene, –78→20 °C, 48 h.

The next step was N-acetoacetylation of the amino-nitro compound 6a, which was initially attempted as described earlier, using thermolysis of the diketene-acetone adduct (pyridinium toluene-4-sulfonate, toluene reflux, 3 h), but starting material was recovered. As an alternative acylating agent we employed S-tert-butyl 3-oxobutanthioate 14, itself generated by base treatment of 2-methylpropane-2-thiol (NaH, THF, –15→0 °C) followed by addition of diketene to the thiolate at –5 °C. Thus amino-nitro compound 6a and the thioester 14 were reacted in the presence of silver(I) trifluoroacetate (THF in the dark) but starting carbamate 6a was recovered. We reasoned this was due to reduced nucleophilicity of the carbamate N-atom, so we removed the tert-butyloxycarbonyl group (TFA, followed by 2M hydrochloric acid) to afford the stable amine hydrochloride salt 15 (Scheme 5). Acylation was completed using both protocols described above, to afford the acetoacetamide 16 (68% from diketene-acetone adduct; just 19% from thioester 14). The precursor functionality for generation of the required dipole (nitrile oxide from dehydration of the primary nitro group) and dipolarophile (enamine derived from the β-ketoamide) is present in the acetoacetamide 16. The next step was planned to be the enamine formation, so the amide 16 was treated with pyrrolidine in toluene at reflux under Dean-Stark water removal conditions. After workup, a product was recovered (55%) but the ¹H NMR spectrum was missing the CH₃ and CH signals expected for the enamine 17, although it did show signals for the pyrrolidine ring. The structure was revealed by an X-ray crystal structure determination to be the unexpected mixed urea 18 (Figure 2). The solid-state structure displays two independent molecules in the asymmetric unit, differing in the detailed conformation of the pyrrolidine sub-unit and linked via a strong N–H⋯O hydrogen bond. Authors, we changed the "Figure 1" on page 5 to the "Figure 2" because you have the "Figure 1" on page 1.
Scheme 5. Attempted enamine formation from acetoacetamide 16. Reagents: i, TFA, 20 °C, 4.5 h, then 2M HCl aq., 20 °C, 0.5 h; ii, Et₃N, DCM, then 2,2,6-trimethyl-1,3-dioxin-4-one, pyrH⁺ OTs, toluene reflux; iii, Et₃N, DCM, then MeCOCH₂COSBut, CF₃CO₂Ag, THF, −15 °C, 30 min; iv, pyrrolidine, toluene, Dean-Stark reflux.

Figure 2. X-Ray crystal structure of mixed urea 18. The structure comprises two independent molecules differing in conformation of the pyrrolidine unit. N(5)–H(5)···O(1): d(D...A) = 2.917(2) Å, <(DHA) = 155(2)°; N(2)–H(2)...O(4): d(D...A) = 2.889(2) Å, <(DHA) = 160(2)°, generating chains parallel to b; ′ = −x,y+1/2,−z+1/2.

We propose the mechanism shown in Scheme 6 wherein the iminium ion formed en route to the desired enamine 17, or in equilibrium with it, is attacked by a second pyrrolidine molecule to promote a retro-Claisen reaction, affording the observed urea and presumably the pyrrolidine enamine of propanone as an unusual leaving group, although this was not isolated.
Scheme 6. Possible mechanism for formation of mixed urea 18.

An alternative potential sequence towards an intramolecular dipolar cycloaddition would be nitrile oxide formation and then cycloaddition to the enol form of the β-keto amide. With this in mind we treated the nitro compound 16 under several reported dehydration conditions: di-tert-butyl dicarbonate\textsuperscript{16} or ethyl chloroformate\textsuperscript{17} (Et\textsubscript{3}N, 0.1 mol equiv. 4-DMAP, in DCM, acetonitrile or toluene at reflux), but in all cases starting material was recovered unchanged. Likewise, an attempt to form a silyl nitronate as dipole (TMSCl, Et\textsubscript{3}N, in THF or acetonitrile at reflux) returned starting nitro-amide 16.

Conclusions

In conclusion, based on these explorations we have not been able to form the isoxazole building block 2 via an intramolecular approach, and continued to focus instead on developing the pyrroloisoxazole strategy towards masked acyltetramic acids via the previously reported intermolecular sequence.
