The synthesis, crystal structures and photophysical properties of two types of pyrene-cored blue-light emitting [4]helicenes (7 and 9) are reported. The chemical structures of all synthesized compounds were fully confirmed by their 1H and 13C NMR spectra, mass spectroscopy as well as elemental analysis. Single-crystal X-ray analysis of these [4]helicenes revealed that there are two types of laterally naphthalene annulated helical architectures, which are clearly influenced by the difference of the R-substituents. The photophysical properties of the [4]helicenes (7 and 9) were fully investigated in both solution and film, along with the pre-cyclization products, 4,9- and 4,10-bis(phenylethenyl)pyrenes (6 and 8). Notable optical features were obtained in these compounds, that make them might be promising candidates for several important applications in modern electronic and optoelectronic devices, such as blue emitters in organic light-emitting devices (OLEDs), or as models for further exploring the development of a new generation of organic materials base on pyrene.

Introduction

Helicenes and helicene-like molecules have received much consideration as academic curiosities because of their twisted shape which results from the repulsive steric overlap of the terminal aromatic nuclei.1 Due to their unique structural properties, like ortho-condensed aromatic rings, which have a powerful, inherently chiral, chromophore and the possibility of electronic interaction,2 the scientific interests of the helicenes are now revising. Recently, these helically shaped molecules have been found many important applications, such as useful component in chiral discotic liquid crystalline materials,3 building blocks for helical conjugated polymers,4 sensors5 and dyes5 in molecular recognitions, and more fascinatingly as catalysts or ligands in asymmetric synthesis,6 and very recently, as blue emitters in OLEDs.7 Thus, there is a sudden surge of interest for exploring novel helicenes with unique optoelectronic properties through new synthetic protocols.

Much recent efforts have been devoted to the development of new synthetic procedures, and the procedures are now continuously improving.1,8 Classical available methods for the synthesis of the helicenes are of the Friedel-Crafts approach to fuse rings reported by Newman and co-worker19 and the photochemically mediated cyclization of stilbene derivatives developed by Martins and co-workers.8b,9 The two methods have recently been optimized and widely applied. Although many [n]helicenes consisting of fused aromatic rings, including benzene,10 thiophene,11 and benzothiophene,12 have previously been reported, to our knowledge, there have only a few reports13 on the [n]helicenes, in which a large π-conjugated polycyclic aromatic hydrocarbons (PAHs) core, such as pyrene, was used to construct the helical structures. Recently, as a part of our research program on the construction of the pyrene-cored π-conjugated [n]helicenes, we successfully prepared a series of 4,5-naphthalene annulated pyrenes14 by using an oxidative intramolecular photocyclization, in which the [4]helicene15 structures are contained. Thus, there is a continuous interest to extend more higher members of helicene frameworks, such as to prepare new [n]helicene motifs around the pyrene core through novel procedures and techniques. Moreover, we select pyrene as the helical core because pyrene molecule has excellent fluorescence...
features\textsuperscript{16} that make pyrene and pyrene derivatives are the commonly used fluorescence probes/sensors.\textsuperscript{17} Our final goal is to develop a new class of pyrene-based polycyclic aromatic hydrocarbons (PAHs) with unique optoelectronic properties for applications in optoelectronic devices.

Despite various approaches that are now available, there is no efficient method to construct phenanthrene annulated pyrene helicenes at the 4-, 5-, 9-, and 10-positions. On the other hand, it is well known that electrophilic substitutions of pyrene only occur at 1-, 3-, 6-, and 8-positions but not the other positions (2, 4, 5, 7, 9, and 10), therefore, pyrene substituted at the latter positions must be prepared in ways other than by the direct electrophilic substitution of pyrene itself.\textsuperscript{18} For example, Moyle and co-worker\textsuperscript{19} have prepared the 4,9-diethylpyrene in a low total yield from ethyl benzene by 14 steps using Friedel-Crafts intramolecular acylation to construct a pyrene ring. Thus, there is substantial interest to investigate the selective introduction of substituents at 4-, 5-, 9-, and 10-positions in the pyrene ring. Along this line, we report here the synthesis, crystal structures and photophysical properties of two types of pyrene-cored blue-light-emitting [4]helicenes (\textit{7} and \textit{9}) by our previously reported intramolecular photocyclization,\textsuperscript{14} starting from 2,7-di-tert-butyl-4,9-bis(phenylethenyl)pyrene (\textit{6}) and 2,7-di-tert-butyl-4,10-bis(phenylethenyl)pyrene (\textit{8}), respectively (Scheme 1, 2 and 3).

\section*{Results and discussion}

\subsection*{Synthesis and characterization}

According to our previously report, we readily obtained the intermediates, 2,7-di-tert-butylpyrene-4-carbaldehyde 2, 2,7-di-tert-butylpyrene-4,9-biscarbaldehyde 3 and 2,7-di-tert-butylpyrene-4,10-biscarbaldehyde 4 in high yields (Scheme 1).\textsuperscript{20} In the present work, we used the difomylated products 3 and 4 as the starting materials for the preparation of the pyrene-cored blue-light emitting [4]helicenes.

We fully determined the chemical structures and purities of these new pyrene-cored [4]helicenes \textit{7} and \textit{9} by their \textsuperscript{1}H/\textsuperscript{13}C NMR spectra, mass spectroscopy and elemental analysis. All compounds are very soluble in common organic solvents, such as hexane, CH\textsubscript{2}Cl\textsubscript{2}, CHCl\textsubscript{3}, and toluene. Thermal properties of \textit{7a–c} and \textit{9} were investigated by thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) measurements. The decomposition temperatures (\textit{T}_d) of the pyrenes \textit{7a–c} and \textit{9} were in the range of 327–395 °C corresponding to a 5% weight loss, and the melting points of \textit{7a–c} and \textit{9} were in the range of 244–261 °C. The key thermal data of the [4]helicenes \textit{7a–c} and \textit{9} are summarized in Table 2.

X-Ray molecular structures and crystal packing

In order to investigate the nature of the molecular structures of the newly developed pyrene-cored [4]helicenes in the solid state, we obtained suitable crystals of 7b, 7c and 9 by using binary solvent systems with vapor diffusion of hexane into dichloromethane solutions. The crystallographic data for the compounds 7b, 7c and 9 are summarized in Table S1 (see ESI†). The helicene 7b lies on a two-fold axis (Fig. 1). For this structure, where slight structural disorder was observed the accuracy of the molecular geometry is lower, though in general sufficient to draw some conclusions. The molecular geometry of the helical skeleton contains short and long C–C bonds. The longer bonds are those mostly affected by the intramolecular torsion (namely, C11–C12, C12–C13, C13–C14, C14–C15), average of 1.43 Å. It is noteworthy to point out that in the peripheral rings, the C20-C21 bond length [1.363(4) (Å)] is significantly shorter than counterpart C8–C9 [1.460(5) (Å)], showing a more twisted structure of peripheral rings because of the rigid pyrene core. The torsion angles along the inner helical rim of upper limbs C11–C12–C13–C14 and C12–C13–C14–C15 are 18.6(5)° and 19.9(5)°, respectively, and the torsion angles along the inner helical rim of lower limbs C26–C27–C28–C29, and C27–C28–C29–C30 are –18.5(5)° and –21.5(5)°, respectively. Nonbonding distances (Å) were calculated as: C37–O1: 5.951 Å; C25–C1: 5.397 Å; and C26–C3: 2.991 Å. These values are also a convenient measure of the helicity. Similar molecular geometry of the helical skeleton for 7c was also observed with corresponding torsion angles along the inner helical rims of the lower limbs C3–C4–C5–C6, C2–C15–C16–C17, and C10–C9–C8–C7, and C9–C8–C20–C21 being 21.8(3), 34.5(3), 19.2(3) and 33.2(3)°, respectively. These values show a more twisted conformation due to the bulkier Me group at C21 and C29 in 7c, compared with H at C15 and C30 in 7b. Similarly, as shown in Fig. 1, the molecular geometry of the helical skeleton for 9 also contains short and long C–C bonds. For example, the longer bonds (namely, C4–C3, C3–C2, C2–C1, C1–C0) also average 1.43 Å, which is mostly caused by the intramolecular torsion. In the peripheral rings, the bond lengths of C15–C16 [1.356(5) (Å)] and C24–C25 [1.348(5) (Å)] are significantly shorter than counterparts of C8–C9 [1.460(5) (Å)] and C31–C32 [1.444(5) (Å)] respectively, showing a more twisted structure of the peripheral rings. For the crystal structural conformation of 9, the torsion angles along the inner helical rim of right limb C4–C3–C2–C1 are –29.2(5)° and –19.4(5)°, respectively, and the torsion angles along the inner helical rim of the left limb C6–C7–C8–C9, and C7–C8–C9–C10 are 24.3(5)° and 19.4(5)°, respectively. Therefore, 7b shows somewhat of the desired pyrene-cored [4]helicene like configurations, in which the two naphthalene-fused [4]helicene-like structures linked in the pyrene ring point away from each other (Fig. 1); in contrast, in the crystal conformations of 7c and 9, the naphthalene-fused [4]helicene arranged in the pyrene ring are located to the same side to form the other type of pyrene-cored [4]helicene. The result obtained in the crystal of 9 is probably due to the strong repulsion between the two terminal methoxy groups and the bulky tert-butyl group. Thus, the structural configuration with lower intramolecular tension is established. Moreover, the different crystal structural conformations in 7b–c and 9 should significantly affect the photophysical properties of these newly developed pyrene-cored [4]helicenes in both solution and in the solid state. Previously, the crystal packing of pyrene molecules has been fully studied. A card-packed structure was observed and the molecules exhibit interplanar separation of ca. 3.5 Å with strong π-π stacking by the involvements of 14 carbons in π-π interactions. As shown in Fig. 2 and Fig. S20 (see ESI†), the present helicenes 7b, 7c and 9 are packed in herringbone pattern. However the overall arrangement of the molecules in the crystal lattice shows pattern

Fig. 1 Molecular structures and conformations for the [4]helicenes 7b, 7c and 9: (I) top views for 7b, 7c and 9, respectively; (II) side views for 7b, 7c and 9, respectively.
of the ladder-like arrays. Interestingly, the intermolecular distances between the pyrenyl planes of two adjacent molecules in 7b, 7c and 9 are ca. 6.22 Å, 6.43 Å and 4.29 Å, respectively, which are not especially short at ca. 3.50–3.70 Å,24 implying the two bulky tert-butyl groups attached in the pyrene rings at 2- and 11-positions played a key role in suppressing the face-to-face π-π stacking in the solid state.25 These longer interplanar distances, which are due to the presence of the bulky tert-butyl groups, could also explain their greater solubility. Interestingly, the parallel pseudo-stacking between the pyrenyl and sideways aromatic rings were observed in the crystal packing of 7b, 7c and 9, respectively. In crystal packing of the helicenes 7b, 7c and 9, the pyrenyl and lateral rings of adjacent molecules lies on planes at the average distance of short contact ca. 3.31 Å for 7b, 5.40 Å for 7c and 3.59 Å for 9, respectively, which is suggestive of partial but remarkable intermolecular interaction leading to the strong herring-bone array of molecules in crystal lattices (Fig. 2). Moreover, a comparison of the characteristic \(^1\)H NMR spectra of 7 and 9 further suggested that the [4]helicene 9 was synthesized in the conformation in which both naphthalene-fused helical rotates are arranged in the same side sense (Fig. 1). On the other hand, further investigations on: i) The effects of introduced methyl groups in the jord regions of the helical molecule 7c; and ii) The studies on both the possibility of Van der Waals interactions and patterns of crystal packing for the compound 7d via single-crystal X-ray crystallography analysis are underway in our laboratory.

### Photophysical and Electrochemical properties

Firstly, we measured the UV/vis absorption and fluorescence spectra of both the newly developed [4]helicenes (7a–c and 9) and the pre-cyclization products, 4,9- and 4,10-bis(phenylethenyl)pyrenes (6 and 8) in dilute dichloromethane solution at room temperature, and the results are presented in Table 1, together with those of the 2,7-di-tert-butylylene (1).14 The comparative UV/vis absorption spectra of the [4]helicenes (7a–c and 9) and the 4,9- and 4,10-bis(phenylethenyl)pyrenes (6 and 8) are shown in Fig. 3 and Fig. 4, respectively. For the 2,7-di-tert-butylylene 1, the absorption spectra is almost identical compared with that of the parent pyrene24 with three well-resolved, sharp absorption band observed in the region 300–350 nm. The slight bathochromic shift is ascribed to the increased electron density on the pyrene ring arising from the electron-donating nature of the tert-butyl groups at the 2- and 7-positions.20 However, for the UV/Vis absorption spectra of the pre-cyclization products, 6 and 8, all spectra are broad, less well resolved and the longest wavelength hyperchromic absorption maxima occur at 370 nm for 6a, 374 nm for 6b, 372 nm for 6c, and 350 nm for 8, respectively (Table 1), which are bathochromically red-shifted by ca. 11–35 nm compared with that of 1, arising from the two phenylene-vinylene chromophores that introduced in the pyrene ring at 4,9- or 4,10-positions (Fig. 3). Interestingly, among the UV/vis absorption spectra of the 4,9-isomer 6 and the 4,10-isomer 8, the latter shows less bathochromically red shift (ca. 11 nm) (Fig. 4). A reasonable explanation for these different shifts is that there are quite different conjugation lengths and conjugation pathways in the two molecular systems. In addition, among the compounds 6, the methoxy-substituted phenylethenylpyrene 6b displays the largest bathochromic shift of the absorption band, which can be attributed to the strongest electron-donating nature of the methoxy group compared to the –H (6a) or –1,3-dimethyl (6c) substituents. The result further demonstrates that the effects of substitution are observed in the UV/vis absorption spectra of 6, for example, with the increase in the electron-donating nature of the substituents, the spectra was found to be more bathochromically red shifted, i.e. 6a < 6c < 6b. On the other hand, for the UV/Vis absorption spectra of the [4]helicenes 7a–c and 9, the profiles of these spectra are almost identical and the absorption bands were observed in the range of 280–410 nm (Fig. 2).
which showed a large number transition bands typically for the PAHs. However, the profiles of the UV/Vis absorption spectra of the cyclized products 7a–c and 9 are quite different with those of the pre-cyclization products 6 and 8, which could be ascribed to the expanded conjugation of the π-electron systems of PAHs after the cyclization reaction. Therefore, the pronounced decrease (hypochromic absorption) of absorption bands in the ranges of 340–410 nm after cyclization are attributed to the absence of the phenylethynyl units, the decrease of aromaticity and the increase of distortions form the plane. Furthermore, the departure from co-planarity with the aromatic ring is also pronounced with methoxy substituents groups, which is ascribed by the absorption bands at 406 and 404 nm for 7b and 9, respectively. Thus, the absence of the bands over 400 nm in the UV/Vis absorption spectra of 7c confirms the increased non-planarity of the aromatic ring to avoid the steric crowing by the overlapping at the C1,10 protons in the pyrene ring and the methyl groups at C9,18 leading to increased strain in these systems.14,25

Table 1 Optical UV-Vis and emission spectroscopic data for 6a–c, 7a–c, 8 and 9 in CH2Cl2 (~10–5–~10–6 M) at 25 °C, compared with that of 2,7-di-tert-butylpyrene 1.

Fig. 3 Normalised UV/Vis absorption spectra of 6 and 7a–c recorded in CH2Cl2 at ~10–6 M concentration at 25 °C, compared with that of 2,7-di-tert-butylpyrene 1.

Fig. 4 Normalised UV/Vis absorption spectra of 8 and 9 recorded in CH2Cl2 at ~10–6 M concentration at 25 °C, compared with that of 2,7-di-tert-butylpyrene 1.
spectroscopic data are summarized in Table 2. The normalized UV/Vis absorption spectra and emission spectra of 7a–c and 9 are shown in Fig. 7 and Fig. S21 (see ESI†), respectively. As shown in Fig. 7, compared to the corresponding spectra in solution, for 7b and 9, a small bathochromic shift (~3 nm) was observed in each molecule, which indicates that these two compounds have similar conformations in both states,27 however, for 7a and 7c, a obvious vibronic absorption band was observed with larger bathochromic shift (~15–20 nm) in the range of 350–400 nm in each compound. These hypsochromic shifts going from solution to films are probably due to both the presence of strong intermolecular π–π aggregations and different molecular conformations. An interesting fluorescence phenomenon was found in the emission spectra of 7a–c and 9 in Fig. S21 (see ESI†). All emission spectra show two regions of interest. For 7a, there is a set of partially resolved bands across the λ = 400–460 region but the spectra are dominated by a feature-less band centred at 384 nm, while for 7b, 7c and 9, there are two sets of both a resolved maximum band at 431 nm for 7b, 427 nm for 7c and 412 nm for 9, and a well-resolved band centred at 508 nm for 7b, 481 nm for 7c and 508 nm for 9, respectively. Based on previous work on pyrene derivatives,28 the higher-energy bands can be attributed to monomer emission, whereas the lower-energy bands can be assigned to excimer emissions. The results are also well consistent with the single-crystal X-ray analysis and the UV/Vis absorption spectra. We further examined the fluorescence emission spectra of 7a–c and 9 in thin films doped into polymethylmethacrylate (PMMA) at the 1 wt% level.29 We observed a deep-blue emission with a maximum peak at 401 nm for 7a, 406 nm for 7b, 421 nm for 7c, and 407 nm for 9 (Fig. 8), respectively, which is almost identical to the corresponding emission in solution, indicating the formation of strong intermolecular π–π aggregations of pyrene units can be suppressed in the doped films. The results suggest these newly developed [4]helicenes 7a–c and 9 might be promising candidates in the fabrication of host-guest-based OLEDs.30 All data are also presented in Table 2.

The fluorescence quantum yields of 7a–c and 9 recorded in dilute dichloromethane solution (~10−6 M) and thin films at room temperature are also summarized in Table 1 and 2, respectively, together with those of 1, 6 and 8. We found the Φf values of the precyclization products 6 and 8 were quite high ranging from 0.77 to 0.85, while the Φf values of the cyclized [4]helicenes 7a–c and 9 were moderate ranging from 0.06 to 0.23. A possible explanation for this is: For these [4]helicenes, 7a–c and 9, low quantum yields were obtained in solution and the thin neat films, which indicates that excitons were not confined to the whole backbone of these molecules due to its non-planar molecular structures. Some energy loss might happen during the exciton migrations,31 thereby resulting in low quantum yields. In contrast, for the pre-cyclization compounds, 6 and 8, high fluorescence.

Fig. 5 Normalised emission spectra of 6 and 7a–c recorded in CH2Cl2 at ~10−6 M concentration at 25 °C, compared with that of 2,7-di-tert butylpyrene 1.

Fig. 6 Normalised emission spectra of 8 and 9 recorded in CH2Cl2 at ~10−6 M concentration at 25 °C, compared with that of 2,7-di-tert butylpyrene 1.
quantum yields were found in solution, indicating the excitons were completely confined to the whole backbone of 6 and 8, arising from the significantly expanded \( \pi \)-delocalization between the rigid phenylethenyl groups and the central pyrene core, thereby giving higher quantum yields.

Finally, we investigated the electrochemical characteristics of the pyrenes 7a–c and 9 by using cyclic voltammetry (CV). The pyrenes were scanned positively, separately, in 0.10 M tetrabutylammonium perchlorate (Bu4NClO4) in anhydrous dichloromethane with a scan rate of 50 mV s\(^{-1}\) at room temperature. We find that the oxidation of the pyrenes was quasi-reversible or reversible processes (Fig. S22, see ESI†). The half-wave potentials for oxidation were 1.49, 1.45, 1.38, and 1.42 V (vs Fe/Fe\(^+\)) for 7a, 7b, 7c, and 9, respectively. From the lowest-energy absorption edge of the UV-vis absorption spectra in thin films, the band gaps (\( E_g \)) of the pyrenes were 3.06, 2.99, 3.04, and 3.01 eV for 7a, 7b, 7c, and 9, respectively. Thus, according to the equation,\(^{32} \) IP = \((E_{\text{onset}})^{\text{ox}} + 4.4\) eV, where [\( E_{\text{onset}}^{\text{ox}} \)]\(^{\text{ox}}\) is the half-wave potentials for the oxidation of the pyrenes versus the reference electrode. The lowest unoccupied molecular orbital (LUMO) and highest occupied molecular orbital (HOMO) of the pyrenes were LUMO: 2.83, 2.86, 2.74, 2.81; HOMO: 5.89, 5.85, 5.78, and 5.82 eV for 7a, 7, 7c, and 9, respectively. It was observed that the \( E_g \) values of 7a–7c varied slightly due to the difference of the R-substituents, and indicates that different substituents in these pyrenes can inevitably result in different energy states of the whole molecule. Furthermore, the calculated HOMO values of 7a–c and 9 vary slightly in the range –5.89 to –5.78 eV, indicating that the materials are promising deep-blue emitters for applications in OLED-like optoelectronic devices.\(^{33} \) All data of electrochemical characteristics for the pyrenes 7a–c and 9 are also summarized in Table 2.

**Conclusions**

In conclusion, we have developed two types of new pyrene-cored blue-light emitting [4]helicenes via intramolecular photocyclisation in good yields and fully characterised the special chemical structures. The single-crystal X-ray analysis revealed that the terminal substituents groups (i.e. methoxy and dimethyl) and the two tert-butyl groups played the key roles for constructing the formation of the helical conformations. These longer interplanar distance, which are due to the presence of the sterically bulky tert-butyl groups, could also explain their greater solubility. Furthermore, the results obtained through inspecting the absorption and emission spectra of the phenylethenyl-functionalised molecules (6 and 8) in solution, and the helical molecules (7a–c and 9) in both solution and the solid state demonstrated that both of them exhibited bright fluorescent emissions from deep-blue to sky-blue visible regions with notable optical features, that make them potential candidates for several important applications in modern electronic and optoelectronic devices, such as blue emitters in OLEDs, or as models for further investigating the development of a new generation of pyrene-based organic materials.

**Experimental**

**General**

\(^1\)H and \(^13\)C NMR spectra were recorded on JEOL 300 (300 MHz and 75 MHz) spectrometers. Mass spectra were obtained on a Nippon Denshi JMS-HX110A UltraHigh Performance Mass Spectrometer at 75 eV using a direct-inlet system. Elemental analyses were performed with a Yanaco MT-5 analyser. Thermogravimetric analysis (TGA) was undertaken using a SEIKO EXSTAR 6000 TG/DTA 6200 unit under nitrogen atmosphere at a heating rate of 10 °C min\(^{-1}\). Differential scanning calorimetry (DSC) was performed using a Perkin-Elmer Diamond DSC Pyris instrument under nitrogen atmosphere at a heating rate of 10 °C min\(^{-1}\). UV-Vis-NIR spectra were recorded using Shimadzu UV-3150 UV-vis-NIR spectrophotometer. Photoluminescence spectra were obtained using a FluoroMax-2 (Jobin-Yvon-Spix) luminescence spectrometer. Electrochemical properties of HOMO and LUMO energy levels were determined by Electrochemical Analyzer.
Materials. Preparation of 2,7-di-tert-butylpyrene (1) was previously described.18

Formylation of 2,7-di-tert-butylpyrene (1) with Cl3CHO Me in the presence of AlCl3: To a stirred solution of 1 (5 g, 16.00 mmol) and dichloromethyl methyl ether (20 mL, 224.00 mmol) in CH2Cl2 (150 mL) was gradually added a powdered aluminum 2,7-di-E,E) g) with hexane : ethyl acetate (5 : 1) as eluents to give light-residue was chromatographed over silica gel (Wako C-300, 200 g) with a toluene as eluent afforded a mixture of 2,7-di-E,E)-butylpyrene-4,9-biscarbaldehyde 3 (3.3 g, 55%) as pale yellow prisms. M.p. 247 °C. 1H NMR (300 MHz, CDCl3): δ = 1.63 (s, 18H, t-Bu), 8.44 (d, 2H, J = 1.8 Hz, Ar-H1a), 8.60 (s, 1H, Ar-H2b), 9.91 (5 d, 2H, J = 1.8 Hz, Ar-H3a), 10.53 (2H, CHO) ppm. MS (EI): m/z: 370 [M+]. C35H32O2 (508.71): calcd. C 87.60, H 7.31; found C 87.60, H 7.37.

On the other hand, the filtrate was evaporated to leave the residue which was chromatographed over silica gel (Wako, C-300; 200 g) with a toluene as eluent afforded a mixture of 2,7-di-E,E)-butylpyrene-4,9-biscarbaldehyde 3 and 2,7-di-E,E)-butylpyrene-4,10-biscarbaldehyde 4, in which ratio is determined as 50 : 50 by 1H NMR spectrum. Although several attempted isolations of 2,7-di-E,E)-butylpyrene-4,10-biscarbaldehyde 3 in pure failed, the compound 4 was easily confirmed by its 13C NMR spectra and GC analysis in the mixture, and thus, the crude was directly used to the next Wittig reaction. 1H NMR (300 MHz, CDCl3): δ = 1.62 (s, 9H, t-Bu), 1.64 (s, 9H, t-Bu), 8.51 (s, 2H, Ar-H9a), 8.57 (s, 2H, Ar-H9b), 9.83 (2H, Ar-H-9a), 10.56 (2H, CHO) ppm.

Synthesis of (E,E)-2,7-di-tert-butyl-4,9-bis(phenylethenyl)pyrene (E,E)-6a: The Wittig reagent was prepared from triphenylphosphine and 3,5-dimethylbenzyl bromide in dry benzene. To a solution of this Wittig reagent (2.5 g, 6.00 mmol) in dry THF (15 mL) was slowly added n-butyl lithium in hexane (3.5 mL, 6.00 mmol) at 0 °C under argon. The mixture was stirred for 10 minutes and a solution of 2,7-di-tert-butylpyrene-4,9-biscarbaldehyde 3 (371 mg, 1.00 mmol) in dry THF (15 mL) was injected into this mixture under same conditions. The mixture was heated to room temperature stirring for 6 h under argon. The mixture was quenched by large amount of water, extracted with dichloromethane (2 x 100 mL), the combined extracts were washed with water and dried with MgSO4 and concentrated. The residue was chromatographed over silica gel (Wako C-300, 200 g) with hexane as eluent to give light-yellow solids. Recrystallization from hexane afforded (E,E)-2,7-di-tert-butyl-4,9-bis(4-methoxyphenylethenyl)pyrene (E,E)-6b (475 mg, 82%) as light-yellow prisms. M.p. 230 °C; 1H NMR (300 MHz, CDCl3): δ = 1.60 (s, 18H, t-Bu), 3.85 (s, 9H, OMe), 7.00 (d, 4H, J = 8.7 Hz, Ar-H1b), 7.35 (5 d, 2H, J = 15.9 Hz, -CH=CH2), 7.64 (4d, 4H, J = 8.7 Hz, Ar-H2b), 7.91 (d, 2H, J = 15.9 Hz, -CH=CH2), 8.24 (2H, 2H, J = 15.9 Hz, Ar-H1a), 8.27 (2H, 2H, J = 15.9 Hz, Ar-H2a), 8.47 (3H, 2H, J = 15.9 Hz, Ar-H8b) ppm. 13C NMR (75 MHz, CDCl3): δ = 32.0, 35.4, 55.4, 114.3, 118.4, 122.5, 122.7, 124.3, 124.8, 128.0, 129.6, 130.7, 131.1, 131.4, 134.7, 148.5, 159.5 ppm. MS (EI): m/z: 578 [M+]. C35H32O2 (578.78): calcd. C 87.16, H 7.31; found C 87.15, H 7.32.

Synthesis of (E,E)-2,7-di-tert-butyl-4,9-bis(3,5-dimethylphenylethenyl)pyrene (E,E)-6c: The Wittig reagent was prepared from triphenylphosphine and 3,5-dimethylbenzyl bromide in dry benzene. To a solution of this Wittig reagent (1.4 g, 3.00 mmol) in dry THF (15 mL) was slowly added n-butyl lithium in hexane (1.87 mL, 3.00 mmol) at 0 °C under argon. The mixture was stirred for 10 minutes and a solution of 2,7-di-tert-butylpyrene-4,9-biscarbaldehyde 2 (372 mg, 1.00 mmol) in dry THF (15 mL) was injected into this mixture under same conditions. The mixture was heated to room temperature stirring for 6 h under argon. The mixture was quenched by large amount of water and extracted with dichloromethane (2 x 100 mL). The combined extracts were washed with water and dried with MgSO4 and concentrated. The residue was chromatographed over silica gel (Wako C-300, 200 g) with hexane as eluent to give desired compounds (NMR analysis) as yellow solids. Recrystallization from toluene and hexane afforded (E,E)-2,7-di-tert-butyl-4,9-bis(3,5-dimethylphenylethenyl)pyrene (E,E)-6c (432 mg, 75%) as yellow solid. M.p. 206 °C. 1H NMR (300 MHz, CDCl3): δ = 1.61 (s, 18H, t-Bu), 2.41 (s, 12H, Me), 7.00 (s, 2H, Ar-H), 7.31 (s, 4H, Ar-H), 7.34 (d, 2H, J = 15.9 Hz, -CH=CH2), 7.80 (d, 2H, J = 15.9 Hz, -CH=CH2), 8.26 (s, 4H, d, Py-H2,6,8,10) ppm. 13C NMR (75 MHz, CDCl3): δ = 21.4,
Synthesis of (E,E)-2,7-di-tert-butyl-4,10-bis(4-methoxophenylethynyl)pyrene (E,E)-8: Separation of compound pure 2,7-di-tert-butyl-4,10-di-formylpyrene by direct method failed by chromatography as well as solvent treatment methods. For this, the mixture (400 mg) of isomers [2,7-di-tert-butylpyrene-4,9-bis(4-carbaldehyde ppm). 13C NMR (75 MHz, CDCl3): MgSO4, filtering and concentrated to dryness on a rotary 2,7-di- 130.7, 131.5, 135.1, 148.5, 149.0, 159.5 ppm. MS (EI): 118.7, 122.1, 123.3, 124.5, 124.6, 124.8, 128.1, 130.1, 130.5, 130.7, 131.5, 148.5, 159.5 ppm. MS (EI): m/z: 578 [M]+. C42H42O2 (578.78): calcd. C 87.16, H 7.31; found. C 87.17, H 7.23. 1H NMR (300 MHz, CDCl3): δ = 1.66 (s, 9H, tBu), 2.36 (s, 6H, Me), 2.63 (s, 6H, OMe), 3.89 (s, 6H, OMe), 7.00 (d, 4H, J = 8.8 Hz, Ar- H), 7.34 (d, 2H, J = 15.9 Hz, Py-CH=CH2-Ar), 7.64 (d, 4H, J = 8.6 Hz, Ar-H), 7.97 (d, 2H, J = 15.9 Hz, Py-CH=CH2-Ar), 8.19 (s, 2H, Py-H1a) 8.26 (s, 2H, Py-H3a), 8.54 (s, 2H, Pyrene- H5a) ppm. 11C NMR (75 MHz, CDCl3): δ = 30.2, 35.7, 55.4, 114.3, 118.7, 122.1, 123.3, 124.5, 124.8, 128.1, 130.1, 130.5, 130.7, 131.5, 148.5, 159.5 ppm. MS (EI): m/z: 578 [M]+. C42H42O2 (578.78): calcd. C 87.16, H 7.31; found. C 87.17, H 7.30.

General procedure for photocyclization: Photo reactor was a cylindrical glass vessel with an immersion well and two tapered joints, one vertical attached with condenser to which argon source was fitted. Another angled for withdrawal and addition of samples. The vessel was flat bottom to allow a magnetic stirring bar to rotate. The immersion well was a double walled pyrex tube cooled by water and containing high pressure quartz Hg-vapour lamp. Argon gas was bubbled through benzene for 20–30 min. and used to dissolved sample and iodine. The dissolved solutions of sample, iodine and propylene oxide were added to the reaction vessel through angled joint and the lamp was turned on. The reaction was carried out under argon atmosphere. Photoreactions were monitored by 1H NMR and iodine color change. After complete irradiation, work included washing with 15% Na2S2O3: H2O and saturated brine, drying with anhydrous MgSO4, filtering and concentrated to dryness on a rotary evaporator. The residue obtained was washed either through a short column of silica gel or different solvent systems were used to obtain the pure compounds.

Synthesis of 2,11-di-tert-butyl-4,9-bis(3,5-dimethoxyphenylethynyl)pyrene (E,E)-6c (50.0 mg, 0.0960 mmol) in 230 mL of benzene was irradiated in presence of I2 (43.9 mg, 0.17 mmol) and propylene oxide (1.54 mL, 22.02 mmol) for 6 h. Work up and chromatography (30% CH2Cl2 in hexane) gave pale yellow solid. Recrystallisation from dichloromethane and hexane afforded 2,11-di-tert-butyl-8,17-dimethoxytetrabenzo[a,fg,lop]tetracene 7b (34.4 mg, 70%) as colorless prisms. M.p. 249 °C. 1H NMR (300 MHz, CDCl3): δ = 1.66 (s, 18H, tBu), 4.02 (s, 6H, OMe), 7.31 (dd, 2H, J = 2.4, 2.4 Hz, Ar-H), 7.99 (d, 2H, J = 8.8 Hz, Ar-H), 8.02 (d, 2H, J = 8.8 Hz, Ar-H), 8.53 (s, 2H, Ar-H), 8.75 (d, 2H, J = 8.8 Hz, Ar-H), 8.96 (s, 2H, Ar-H), 9.22 (s, 2H, Ar-H) ppm. 13C NMR (75 MHz, CDCl3): δ = 32.0, 35.7, 55.4, 107.8, 117.8, 117.9, 118.9, 123.3, 124.3, 124.5, 128.4, 128.5, 129.0, 129.3, 129.9, 130.2, 147.9, 158.3 ppm. MS (EI): m/z: 574 [M]+. C42H38O2 (574.75): calcd. C 87.77, H 6.66; found C 87.78, H 6.65.

Synthesis of 2,11-di-tert-butyl-7,9,16,18-tetramethyltetrabenz[a,fg,lop]tetracene (7c): (E,E)-2,7-Di-tert-butyl-4,9-bis(3,5-dimethoxyphenylethynyl)pyrene (E,E)-6c (50.0 mg, 0.0960 mmol) in 200 mL of benzene was irradiated in presence of I2 (43.9 mg, 0.17 mmol) and propylene oxide (1.54 mL, 22.02 mmol) for 12 h. After work up and chromatography (30% CH2Cl2 in hexane), the compound thus obtained was further washed with hexane and recrystallized from dichloromethane and hexane to give 2,11-di-tert-butyl-7,9,16,18-tetramethyltetrabenz[a,fg,lop]tetracene 7c (40 mg, 82%) as white solid. M.p. 261 °C. 1H NMR (300 MHz, CDCl3): δ = 1.58 (s, 18H, tBu), 2.36 (s, 6H, Me), 2.63 (s, 6H, Me), 7.37 (s, 2H, Ar-H), 7.72 (s, 2H, Ar-H), 8.02 (d, 2H, J = 8.8 Hz, Ar-H), 8.18 (s, 2H, Ar-H), 8.75 (d, 2H, J = 8.8 Hz, Ar-H), 8.89 (s, 2H, Ar-H) ppm. 13C NMR (75 MHz, CDCl3): δ = 21.3, 24.9, 31.9, 35.6, 117.2, 120.3, 121.6, 125.1, 125.8, 127.7, 127.9, 128.1, 128.9, 129.1, 129.5, 131.8, 134.6, 135.5, 135.8, 147.4 ppm. MS (EI): m/z: 570 [M]+. C42H38O2 (570.80): calcd. C 92.58, H 7.42; found C 92.59, H 7.40.

Synthesis of 2,11-di-tert-butyl-8,17-dihydroxytetrabenzo[a,fg,lop]tetracene (7d): A Schlenk flask was charged with methyl ether 7b (110.1 mg, 0.19 mmol) and flushed with argon. The material was dissolved in dichloromethane (10 mL) and BBr3 in 5 mL dichloromethane, (0.85 mL, 0.85 mmol, 4.5 equiv.) was added drop wise. The mixture was stirred at rt. for 6 h. the mixture was diluted with water (10 mL), extracted with dichloromethane (3 × 20 mL). The organic portion was washed with brine and water and finally dried over anhydrous MgSO4 and solvent was evaporated in vacuo. The residue was washed with hexane and recrystallized in chloroform and hexane to afford 2,11-di-tert-butyl-8,17-dihydroxytetrabenzo[a,fg,lop]tetracene.

Synergy of 2,1,1-di-tert-butyl-8,14-dimethoxytetrazeno[a,f,g, lop]tartarene (9): (E,E)-2,7-Di-tert-butyl-4,10-bis-4-methoxyphenylethylene|pyrene (E,E)-8 (50.0 mg, 0.089 mmol) in 100 mL of benzene was irradiated in presence of I2 (43.6 mg, 0.17 mmol) and propylene oxide (1.54 mL, 22.0 mmol) for 6 h. Work up and chromatography (30% CH2Cl2/Hexane) gave pale yellow solid or as white crystalline solid. Racemisation from chlorofrom and hexane afforded 2,1,1-di-tert-butyl-8,14-dimethoxytetrazeno[a,f,g,l,op]tartarene 9 (34 mg, 70%) as colourless prisms. M.p. 256°C. 1H NMR (300 MHz, CDCl3): δ = 1.58 (s, 9H, -Bu), 1.70 (s, 9H, -Bu), 4.08 (s, 6H, OMe), 7.32 (dd, 2H, J = 2.1, 2.1 Hz, Ar-H), 8.00 (d, 2H, J = 9.0 Hz, Ar-H), 8.06 (d, 2H, J = 8.8 Hz, Ar-H), 8.64 (s, 2H, Ar-H), 8.75 (d, 2H, J = 8.8 Hz, Ar-H), 9.02 (s, 2H, Ar-H), 9.22 (s, 2H, Ar-H) ppm. 13C NMR (75 MHz, CDCl3): δ = 32.0, 35.5, 55.5, 107.9, 110.0, 119.0, 119.1, 122.5, 123.7, 127.4, 127.5, 128.0, 128.9, 129.0, 129.2, 130.0, 132.1, 146.5, 149.0, 158.3 ppm. MS (EI): m/z: 574 [M]+. C26H32O2 (574.75): calcd. C 87.77, H 6.66; found C 87.76, H 6.68.

Crystalline data and refinement details for 7b, 7c and 9

Diffraction data were collected using a Bruker SMART APEX II CCD diffractometer using narrow frames.24 Diffraction data for 7b, 7c and 9 were collected with synchrotron radiation at the ALS, Station 11.3.1. Data were corrected for absorption on the basis of symmetry equivalent and repeated data and for Lp effects. The structures were solved by direct methods (charge flipping for 9) and refined on F2 using all data.25 H atoms were constrained in a riding model. There are two and four molecules in the asymmetric units of 7b, 7c and 9 respectively. Further details can be found in Table S1 and ref. 21.

Supporting information (See also the footnote on the first page of this article): 1H and 13C NMR spectra of 6a-c, 7a-d, 8, and 9. TGA curves of 7a-c and 9, packing diagram of 7b, 7c, and 9. Normalised emission spectra of 7a-c and 9 recorded in thin neat films, cyclic voltamogram (CV) of 7a-c and 9, and summary of crystal data of 7b, 7c and 9.
