## Job Stressors and Voluntary Work Behaviours: Mediating Effect of Emotion and Moderating Roles of Personality and Emotional Intelligence

Journal:	<i>Human Resource Management Journal</i>
Manuscript ID:	13-HRMJ-02359.R2
Wiley - Manuscript type:	Original Article
Keywords:	Emotion, Voluntary work behaviours, Job stressors, Big five personality, Emotional Intelligence
Abstract:	Framed within an emotion-centred model (Spector and Fox, 2002), the current study investigated the mediating role of negative and positive emotion between job stressors and counterproductive work behaviours (CWB) and citizenship behaviours (OCB) and the moderating effects of personality and ability-based emotional intelligence (EI) on the relationships between job stressors and emotions. Results from a sample of 202 Caribbean employees across eight public and private sector organizations showed that both positive and negative emotion mediated the relation between job stressors and citizenship behaviours, whereas only negative emotion was found to mediate the relation between job stressors and CWB. Some, support was found for the moderating effects of personality and emotional intelligence. Implications for research and practice are discussed.

**Job Stressors and Voluntary Work Behaviours: Mediating Effect of Emotion and Moderating Roles of Personality and Emotional Intelligence**

For Review Only

### Abstract

Framed within an emotion-centred model (Spector and Fox, 2002), the current study investigated the mediating role of negative and positive emotion between job stressors and counterproductive work behaviours (CWB) and citizenship behaviours (OCB) and the moderating effects of personality and ability-based emotional intelligence (EI) on the relationships between job stressors and emotions. Results from a sample of 202 Caribbean employees across eight public and private sector organizations showed that both positive and negative emotion mediated the relation between job stressors and citizenship behaviours, whereas only negative emotion was found to mediate the relation between job stressors and CWB. Some support was found for the moderating effects of personality and emotional intelligence. Implications for research and practice are discussed.

**Keywords:** Emotion; Voluntary Work Behaviours; Job stressors; Big Five personality; Emotional Intelligence

## Introduction

Organizational citizenship behaviour (OCB) and counterproductive work behaviour (CWB) are typically seen as discretionary, non-task in nature and, coupled with task performance, represent three broad domains of job performance (Rotundo & Sackett, 2002). In the HR literature, OCB (sometimes termed extra-role behaviour or discretionary work behaviour) has received recent attention (Gong et al., 2010; Frenkel et al., 2012) and is viewed as a HR-related outcome of HRM (Knies & Leisink, 2014). Indeed, OCB "...is seen as the critical factor in linking employee responses to performance..." (Purcell & Hutchinson, 2007: 6). Within the same HR domain, CWB has been considered at the level of specific behaviours such as absenteeism (e.g. Hopkins, 2014) and workplace bullying (e.g. Woodrow & Guest, 2014) as well as the broader CWB concept (e.g. Chao et al., 2011). In the people management-performance causal chain (Purcell & Hutchinson, 2007) discretionary behaviour and attendance (a specific form of CWB) coupled with task behaviour are hypothesised to influence organisational effectiveness.

However, although OCB and CWB are important HR-related outcomes of people management, they have tended to be researched in isolation. Yet with consensus that both behaviours can be conceptualised via distinct subgroups of organisationally and individually directed behaviours (Bennett & Robinson, 2000; Gruys & Sackett, 2003) researchers have become more interested in the commonality between the two constructs and theoretical explanations for why people engage in them (Dalal, 2005; Spector, & Fox, 2010). One such theory, Spector and Fox's (2002) emotion-centred model, postulates that an employee's emotional reactions are induced by their appraisal of the work environment and that induced emotion could lead to OCB or CWB. Positive emotion should produce OCB while negative

1  
2  
3 emotions should produce CWB. Furthermore, personality and perceived control over work tasks  
4  
5 are hypothesized to moderate the relationship between job stressors and emotions. The purpose  
6  
7 of our investigation was to develop further some of the proposed relationships in Spector and  
8  
9 Fox's model. Specifically, we tested the main mediation propositions of positive and negative  
10  
11 emotion as well as including the moderating effects of the Big Five personality traits and ability-  
12  
13 based emotional intelligence (EI). As emotion plays a central role in Spector and Fox's model,  
14  
15 we included EI since an individual's ability to understand and regulate their emotions so as to  
16  
17 attain desired affective states and adaptive outcomes are particularly relevant (Wong & Law,  
18  
19 2002). Figure 1 shows the proposed relationships to be tested in this study.

30 This study constitutes the first effort, to our knowledge, to explore the mediating effect of  
31  
32 positive emotion on the relationship between job stressors and citizenship behaviours; and the  
33  
34 moderating effects of Big Five personality traits and EI on relations between job stressors and  
35  
36 emotions. Moreover, research on the role of emotions, its causes, expression, and consequences  
37  
38 in organizational settings are still vastly fragmented and limited (Brief & Weiss, 2002).  
39  
40 Therefore, this study enhances our theoretical understanding of how the work environment,  
41  
42 emotion and individual differences combine to influence OCB and CWB. Furthermore, such  
43  
44 knowledge would allow HR managers and/or practitioners to better develop appropriate  
45  
46 interventions aimed at reducing negative workplace behaviours such as CWB, and enhancing  
47  
48 positive workplace behaviours such as OCB. Hence, HR policies and practices could be better  
49  
50 directed to achieve more favourable HRM outcomes.

## Theoretical framework

### *Emotion and OCB/CWB*

Emotion is defined as “adaptive behavioural and physiological response tendencies that are called forth directly by evolutionarily significant situations” (Gross, 1998, p. 272). Negative emotions are induced if an individual perceives a situation as threatening to his or her well-being while positive emotions are induced if the individual appraises the situation as enhancing well-being (Lazarus, 1993). Theoretically, Spector and Fox (2002) argue that emotions lead to action tendencies and intentions to reduce negative and enhance positive states. Induced negative emotion is likely to lead to CWB, either to passively and indirectly cope with the emotion or to actively and directly attack the agent of the situation. Whereas, induced positive emotion is likely to produce OCB since positive states are likely to induce approach tendencies to remain in the situation (Spector & Fox, 2002).

Empirically, relationships between job stressors and CWB (Miles, Borman, Spector, & Fox, 2002; Penny & Spector, 2005) and OCB (Miles et al., 2002), as well as between stressors and negative emotion (Fox, Spector, & Miles, 2001; Miles et al., 2002) and positive emotion (Fox, et al., 2001) has emerged. However, whilst the relationship between negative emotion and CWB has generated more support (Fox et al., 2001; Miles et al., 2002), limited support is seen between positive emotion and citizenship behaviours (Miles et al. 2002). Studies have found support for the mediating effect of negative emotion between job stressors and CWB (Fox & Spector, 1999; Fox et al., 2001), but to our knowledge no evidence has emerged supporting the mediating effect of positive emotion between job stressors and OCB. Therefore, we propose:

*Hypothesis 1: Negative emotion mediates the relationship between job stressors and CWB.*

*Hypothesis 2: Positive emotion mediates the relationship between job stressors and OCB.*

### *Personality*

Personality influences appraisal of the stressor and emotional reaction to it, as well as determining if emotion leads to OCB and CWB (Spector and Fox, 2002). A great deal of research has used the Big Five model of personality (Emotional Stability, Extraversion, Openness to Experience, Agreeableness, and Conscientiousness) as an organizing framework for investigating the relationship between personality and important variables such as occupational stressors (Bowling & Eschleman, 2010), and CWB and OCB (Sackett, Berry, Wiemann, & Laczko, 2006).

To tie the research on the Big Five and the stressor-emotion model together, we adopt Gross' (1998) model of emotional regulation as the theoretical basis for our investigation. Emotional regulation refers to the processes by which individuals affect which emotions they have, when they have them, and how these emotions are experienced and expressed (Gross, 1998). Individuals can regulate emotion response tendencies either by using antecedent-focused regulation strategies, which influence whether or not particular emotions are triggered, or response-focused regulation strategies which influenced how emotions are modulated once they have been triggered (Gross, 1998; John & Gross, 2007).

Conscientious individuals are more likely to use antecedent-focused emotional regulation strategies (e.g. deploying attention, and cognitive reappraisal) than non-conscientious individuals (John & Gross, 2007). Gross & John (2003) reported that Conscientiousness correlated positively with cognitive reappraisal –interpreting a potentially emotion-eliciting situation in a manner that modifies its emotional impact before it occurs. Cognitive reappraisal alters the entire subsequent emotion trajectory, including experiencing more positive emotion and less negative emotion

1  
2  
3 (John & Gross, 2007). Thus, conscientious people are more likely to reappraise stressful events,  
4 therefore experiencing low levels of negative emotions and high levels of positive emotions than  
5 non-conscientious people. Given this we hypothesized that:  
6  
7  
8  
9

10 *Hypothesis 3: The relationship between job stressors and negative emotion is stronger*  
11 *when Conscientiousness is low, whereas the relationship between job stressors and*  
12 *positive emotion is stronger when Conscientiousness is high.*  
13  
14  
15  
16

17 Individuals high on Neuroticism are anxious, easily frustrated, insecure (Caspi, Roberts,  
18 & Shiner, 2005), and are more vulnerable to daily stressors than those low on this factor  
19 (Gunthert, Cohen, & Armeli, 1999). John and Gross (2007) postulated that Neuroticism should  
20 be negatively related to antecedent-focused emotional regulation strategies, suggesting that  
21 highly neurotic individuals would engage in fewer, and make less effective attempts at emotion  
22 regulation. As Neuroticism correlates negatively with reappraisal (Gross and John, 2003),  
23 emotionally stable people are more likely to reappraise stressful events and experience low levels  
24 of negative emotions and high levels of positive emotions than non-emotionally stable people.  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 We hypothesized that:  
37  
38

39 *Hypothesis 4: The relationship between job stressors and negative emotion is stronger*  
40 *when Emotional Stability is low, whereas the relationship between job stressors and*  
41 *positive emotion is stronger when Emotion Stability is high.*  
42  
43  
44  
45

46 Extraverts are more likely than introverts to experience positive emotions (Watson &  
47 Clark, 1997) and to express both positive and negative emotions (Gross & John, 1998).  
48

49 Extraversion has been found to correlate positively with emotional understanding and regulation  
50 (Ciarrochi, Chan, Caputi, 2000) and reappraisal (Gross & John, 2003). Thus, as extraverts are  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 more likely to reappraise stressful events, they experience low levels of negative emotions and  
4  
5 high levels of positive emotions than non-extraverts. Our fifth hypothesis is:

6  
7  
8 *Hypothesis 5: The relationship between job stressors and negative emotion is stronger*  
9  
10 *when Extraversion is low, whereas the relationship between job stressors and positive*  
11 *emotion is stronger when Extraversion is high.*

12  
13  
14  
15 Openness to experience is related to greater awareness, clarity, and intensity of whatever  
16  
17 emotion the individual is experiencing at a given time. Individuals high on openness should feel  
18  
19 optimistic about regulating their emotions; they accept their emotions as real, important, and  
20  
21 generally worth attention and regulation (John & Gross, 2007). People high on Openness to  
22  
23 Experience are more likely to reappraise stressful events (Gross and John, 2003); therefore they  
24  
25 experience low levels of negative emotions and high levels of positive emotions. Hypothesis six  
26  
27 is:  
28  
29

30  
31 *Hypothesis 6: The relationship between job stressors and negative emotion is stronger*  
32 *when openness is low, whereas the relationship between job stressors and positive*  
33 *emotion is stronger when Openness is high.*

34  
35  
36  
37  
38 In terms of regulatory strategies, most effects for Agreeableness would be determined by  
39  
40 the specific interpersonal features of the situation (John & Gross, 2007). Nevertheless, Gross and  
41  
42 John (2003) found Agreeableness to be related positively to reappraisal. Thus, people high on  
43  
44 agreeableness are more likely to reappraise stressful events and are therefore likely to show low  
45  
46 levels of negative emotions and high levels of positive emotions. Given this we hypothesized  
47  
48 that:  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 *Hypothesis 7: The relationship between job stressors and negative emotion is stronger*  
4 *when Agreeableness is low, whereas the relationship between job stressors and positive*  
5 *emotion is stronger when Agreeableness is high.*

### 10 *Emotional Intelligence*

11  
12 The emotional intelligence literature is proliferated with controversies over its  
13 conceptualization and measurement (Davies, Stankov, & Roberts, 1998) with researchers either  
14 adhering to an ability-based (Mayer, Caruso & Salovey, 1999) or trait-based model (Petrides &  
15 Furnham, 2000). In this study, EI is defined as a set of interrelated skills concerning “the ability  
16 to perceive accurately, appraise, and express emotion; the ability to access and/or generate  
17 feelings when they facilitate thought; the ability to understand emotion and emotional  
18 knowledge; and the ability to regulate emotions to promote emotional and intellectual growth”  
19 (Mayer & Salovey, 1997: 10).  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30

31  
32 As before, emotional regulation seems to be a reasonable theoretical basis for the  
33 proposed moderating effect of EI between job stressors and emotion. Brunetto et al., (2012)  
34 argue those low in EI try to control their exposure to negative emotions and when unable to do  
35 so, negative performance outcomes are likely to emerge. High EI individuals should be able to  
36 modulate their response tendencies and have more effective emotion regulation processes so as  
37 to attain desired affective states (Wong & Law, 2002). High EI individuals can make effective  
38 use of antecedent-focused emotion regulation strategies to produce positive emotion and promote  
39 emotional and intellectual growth (Wong & Law, 2002). Based on this, we hypothesized that:  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49

50 *Hypothesis 8: The relationship between job stressors and negative emotion is stronger*  
51 *when EI is low, whereas the relationship between job stressors and positive emotion is*  
52 *stronger when EI is high.*  
53  
54  
55  
56  
57  
58  
59  
60

## Method

### *Participants*

The study comprised 202 employees across eight organizations from the manufacturing, financial, and services private industry and the public sector in Barbados. Of the participants, 101 (50%) were male and 101 (50%) were female, mean age of 35 years (SD = 10.29) and mean tenure of 8.6 years (SD = 8.16). Researchers have argued that heterogeneous populations provide more variation in work characteristics and behaviours than homogenous populations and such variation is “more important than representativeness of the sample under study” (De Lange et al., 2003: 287). The majority of the sample was non-manual workers (56.4%), with 35.1% manual workers and 8.4% in a managerial/supervisory position. Of the employees providing other ratings, 89 (44.1%) were male and 111 (55%) were female. Average age was 35 years (SD = 9.94).

### *Measures*

*Stressors.* Work-constraints were measured by the Organizational Constraints Scale (OCS; Spector & Jex, 1998). The OCS is an 11-item scale indicating how frequently job performance is hindered by constraints such as inadequate training, co-workers, rules and procedures and availability of resources (rating from 1, *less than once per month or never*, to 5, *several times per day*). Spector and Jex (1998) reported a mean Cronbach's  $\alpha$  of .85 across eight samples. Interpersonal conflict was measured by the Interpersonal Conflict at Work Scale (ICAWS; Spector & Jex, 1998). ICAWS is a 4-item scale where participants indicate the frequency of conflict with others at work, ranging from 1 (*never*) to 5 (*Always*). Spector and Jex (1998) reported a mean Cronbach's  $\alpha$  of .74 across thirteen samples. Role Stressors (role ambiguity and role conflict) were measured by Rizzo, House & Lirtzman's (1970) 14-item scale.

1  
2  
3 Role ambiguity was measured by 6-items while role conflict is measured by 8-items. Participants  
4 responded to each item on a 7-point Likert scale ranging from 1 (*strongly disagree*) to 7  
5  
6 (*strongly agree*). Low scores on the role ambiguity subscale represent high role ambiguity and  
7  
8 high scores on the role conflict subscale represent high role conflict.  
9  
10

11  
12 *Emotions.* Van Katwyk et al's. (2000) Job-Related Affective Well-being Scale (JAWS)  
13 was used to assess a wide range of emotions experienced in response to conditions of the job.  
14  
15 Items asked employees to indicate how often they feel each of 30 emotional states by choosing  
16  
17 one of five response choices ranging from 1 (*almost never*) to 5 (*extremely often or always*). A  
18  
19 positive emotion score was obtained by summing scores on the 13 positive affect items; a  
20  
21 negative emotion score was obtained by summing the scores on the 17 negative items. Van  
22  
23 Katwyk et al. reported a Cronbach's  $\alpha$  of .95 for the overall JAWS.  
24  
25  
26  
27  
28

29  
30 *Personality.* The Big Five personality dimensions of Conscientiousness, Extraversion,  
31  
32 Emotional Stability, Agreeableness and Open to Experience were each measured by 10-item  
33  
34 versions of each scale of Goldberg's (1999) Big Five factor markers in the International Item  
35  
36 Pool. The construct validity of this scale has been demonstrated in terms of its relationship with  
37  
38 the corresponding scales in the NEO (Costa & McCrae, 1992). Each item was rated on a 5-point  
39  
40 Likert scale ranging from 1 (*very inaccurate*) to 5 (*very accurate*).  
41  
42  
43

44 *Emotional Intelligence.* The Wong and Law Emotional Intelligence Scale (WLEIS, 2002)  
45 was used to measure ability-based EI. Previous studies support the scale's factor structure,  
46  
47 internal consistency, convergent, and discriminate validity (Law et al., 2004; Wong & Law,  
48  
49 2002). Moreover, this scale has been shown to measure a construct distinct from Big Five  
50  
51 personality (Law et al., 2004; Wong & Law, 2002). The scale consists of four dimensions with  
52  
53 four items in each dimension. The Self-Emotion Appraisal (SEA) dimension relates to  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 individuals' ability to understand and express their emotions. The Others' Emotion Appraisal  
4  
5 (OEA) dimension relates to individuals' ability to perceive and understand the emotions of  
6  
7 others. The Regulation of Emotion (ROE) dimension relates to individuals' ability to regulate  
8  
9 their own emotions. The Use of Emotion (UOE) dimension relates to individuals' ability to make  
10  
11 use of their own emotions by channelling them toward constructive activities to facilitate  
12  
13 performance. Participants responded to each item using a 7-point Likert-type response scale  
14  
15 ranging from 1 = (*strongly disagree*) to 7 (*strongly agree*). High scores represented high ability  
16  
17 emotional intelligence.  
18  
19  
20  
21

22 *OCB and CWB.* The 50-item version of the Voluntary Workplace Behaviour Scale  
23  
24 (VWB) (see Coyne et al, 2013) was used to measure OCB and CWB. The scale assessed a five-  
25  
26 factor model including interpersonal courtesy (e.g. Treated other employees in the organisation  
27  
28 with respect), interpersonal helping (e.g. Given helpful advice to a co-worker), organizational  
29  
30 citizenship behaviours towards the organization (OCBO; e.g. Made suggestions to improve the  
31  
32 organisation), counterproductive work behaviours towards the organization (CWBO; e.g.  
33  
34 Damaged or wasted property, material or company supplies), and counterproductive work  
35  
36 behaviours towards the individual (CWBI; e.g. Been rude and offensive to another employee).  
37  
38 Other raters were asked to rate the extent that their co-worker engaged in citizenship behaviours  
39  
40 and counterproductive work behaviours in the previous 12-months on a six-point Likert scale  
41  
42 from '0 = never' to '6 = very often'.  
43  
44  
45  
46  
47  
48

49 Confirmatory factor analysis (CFA) goodness of fit test statistics provided evidence for  
50  
51 the factor structure of the five factor VWB scale ( $\chi^2 = 202.5$ ,  $df = 80$ ,  $p < .001$ ; RMSEA = .08,  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 CFI = .96, NNFI = .94). Also, CFA was conducted for all other scales in the study and the fit  
4  
5 indices showed reasonable and good fit<sup>1</sup>.  
6  
7

### 8 ***Procedure***

9  
10 Two survey instruments – a self-report questionnaire and peer or co-workers rating  
11  
12 measure of VWB and return envelopes were distributed to participants. Employees were briefed  
13  
14 by the researcher on the purpose of and procedure for the study and were asked to choose a peer  
15  
16 or co-worker who would complete the VWB scale. To preserve confidentiality and anonymity,  
17  
18 employees generated a coded number consisting of 7 digits. Employees then completed the self-  
19  
20 report survey instrument during the session and co-workers who completed the rating  
21  
22 instruments, returned them within two days of the questionnaire distribution, in the sealed  
23  
24 envelope, to a box placed in the Human Resources Department of the organizations. Of the 450  
25  
26 distributed instruments, 202 usable surveys (44.8%) were returned.

### 32 **Results**

33  
34 Descriptive statistics, correlations and Cronbach's alpha reliabilities for each study  
35  
36 variable are presented in Table 1. The alpha coefficients for all measures used were all over the  
37  
38 .70 minimum established by Nunnally (1978) ranging between .80 and .96.  
39  
40

41 Work constraints, interpersonal conflict and role conflict were significantly positively  
42  
43 correlated with CWBO, CWBI, negative emotion, and significantly negatively associated with  
44  
45 courtesy and positive emotion. Role ambiguity was only significantly positively correlated with  
46  
47 negative emotion and significantly negatively associated with positive emotion. Negative  
48  
49 emotion was significantly positively associated with CWB, and significantly negatively  
50  
51 correlated with OCB. Positive emotion was significantly positively correlated with all OCB  
52  
53 factors.  
54  
55  
56

57  
58 <sup>1</sup> Goodness of fit statistics are available on request to the first author for all scales used in the study.

10  
11 We employed the bootstrapping method with bias-corrected estimates based on 5000 re-  
12 samples to test our mediation hypotheses (Preacher & Hayes, 2008). Bootstrapping allowed us to  
13 test the indirect effects of each mediator simultaneously while controlling for other variables in  
14 the model and to compare the effects of the mediators with one another (Preacher & Hayes,  
15 2008). This enabled us to test whether positive and negative emotional reactions represent  
16 different processes and are differentially related to voluntary behaviours. Moreover, the  
17 bootstrapping approach does not rely on a normal sampling distribution and can be applied to  
18 small samples with more confidence (Preacher & Hayes, 2004). Additionally, using the  
19 bootstrapping method reduces the likelihood of Type 1 error as the number of inferential tests is  
20 minimized. For bootstrap analyses, point estimates of indirect effects are considered significant  
21 when zero is not contained in the 95% confidence intervals.

34  
35

36  
37 Bootstrap analyses (Table 2) demonstrated evidence for negative emotion as a significant  
38 mediator between job stressors and CWB in all cases (controlling for positive emotion). Positive  
39 emotion was not found to be a significant mediator between job stressors and CWB (controlling  
40 for negative emotion). The contrast testing whether the two indirect effects differ significantly  
41 was not significant in all cases, indicating that two indirect effects cannot be distinguished in  
42 terms of magnitude. In addition, both positive and negative emotion were significant mediators  
43 between job stressors and citizenship behaviours in all cases except for the role-conflict-helping  
44 relationship. Once again, the contrast testing was not significant in all cases.

Hierarchical moderated regression were computed to test hypotheses 3-8. We followed Aiken and West (1991) and Cohen et al., (2003) guidelines for testing the moderation hypothesis. In step 1, the control variables were entered. In step 2, the centred effects for independent variables were entered. In step 3, the centred effects for moderator variables were entered. In step 4, interaction terms computed using centred predictor and moderator variables were entered.

Results of moderated regression analyses are reported in table 3. We plotted significant interaction terms and reported regression slopes for low (-1 standard deviation) and high (+1 standard deviation) levels of the moderators<sup>2</sup>. Conscientiousness moderated the role ambiguity-positive emotion, work constraints-negative emotion, and role conflict-negative emotion relationships. High role ambiguity was associated with higher levels of positive emotion when conscientiousness was high and high work constraints and role conflict were associated with higher levels of negative emotion when conscientiousness was low (see Figure 1 and 2 for the work constraints data). Emotional stability moderated the role conflict-positive emotion relationship. High role conflict was associated with higher levels of positive emotion, when emotional stability was high. Extraversion moderated the work constraints-negative emotion relationship. High work constraints was associated with higher levels of negative emotion, when extraversion was low.

Agreeableness moderated the role ambiguity-positive emotion and role ambiguity-negative emotion relationships. High role ambiguity was associated with higher levels of positive

---

<sup>2</sup> Only two of the plotted significant interaction terms were included as an illustration. The other plotted significant interaction terms are available on request to the first author.

1  
2  
3 emotion and lower levels of negative emotion, when agreeableness was high. EI was a moderator  
4  
5 in the role ambiguity-negative emotion, interpersonal conflict-negative emotion, and role  
6  
7 ambiguity-positive emotion relationships. High interpersonal conflict and role ambiguity was  
8  
9 associated with lower levels of negative emotion and high role ambiguity was associated with  
10  
11 higher levels of positive emotion, when EI was high. Thus, partial support was provided for the  
12  
13 majority of the moderation hypotheses, with the exception of hypothesis 6. Here, Openness  
14  
15 failed to act as a moderator between job stressors and positive and negative emotion.

### 23 24 25 26 27 **Discussion**

28  
29 This research tested the main propositions of Spector and Fox's (2002) model that an  
30  
31 employee's positive or negative emotional reactions are induced by their perception/appraisal of  
32  
33 the work environment and that induced emotion could lead to OCB or CWB. Positive emotion  
34  
35 should produce OCB while negative emotions should produce CWB. Additionally, we tested the  
36  
37 moderating effects of Big Five personality traits and ability-based EI, on the relationships  
38  
39 between job stressors and positive and negative emotion. Table 4 provides a summary of  
40  
41 supported and non-supported hypotheses.  
42  
43  
44

---

50  
51  
52  
53 From a theoretical perspective, the findings of this study support the premise that work  
54  
55 conditions as perceived by employees lead to emotional reactions, which influence CWB and  
56  
57  
58  
59  
60

1  
2  
3 OCB, thus concurring with the central role of emotion in Spector and Fox's (2002) model.  
4  
5 Firstly, a partial mediating role of negative emotion between job stressors and CWB emerged,  
6  
7 which supports the notion that an employee's negative appraisal of the work environment  
8  
9 induces negative emotion which in turn increases the likelihood of the employee engaging in  
10  
11 CWB. Secondly, positive emotion did not emerge as a significant mediator between job stressors  
12  
13 and CWB, suggesting that induced positive emotion resulting from an employee's positive  
14  
15 appraisal of their work environment will not decrease the likelihood of the employee engaging in  
16  
17 CWB. Thirdly, in eleven of the twelve analyses, both positive emotion and negative emotion  
18  
19 were mediators of the relationship between job stressors and OCB, lending weight to the idea  
20  
21 that an employee's positive appraisal of the work environment induces positive emotion and  
22  
23 increases the likelihood of the employee exhibiting OCB. Moreover, these findings suggest that  
24  
25 negative appraisal of work environment induces negative emotion which in turn inhibits the  
26  
27 likelihood of the employee performing OCB. Thus, mediation analyses provided some evidence  
28  
29 that positive and negative emotional reactions represent different processes and are differentially  
30  
31 related to OCB and CWB.  
32  
33  
34  
35  
36  
37  
38

39 Further, our findings suggest differential relationships between stressors and CWB and  
40  
41 OCB. For instance, interpersonal conflict was more closely associated with CWBI than CWBO  
42  
43 and role conflict and work constraints were more closely associated with CWBO than CWBI.  
44  
45 Moreover, work constraints were more closely related with OCBO than interpersonal helping  
46  
47 and interpersonal courtesy, and interpersonal conflict was more closely associated with  
48  
49 interpersonal helping and interpersonal courtesy than OCBO. These differential relationships  
50  
51 support the target-similarity model (Lavelle et al., 2007) in that perceptions about an entity  
52  
53 predict social exchange with the entity which in turn predicts behaviour towards that entity.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Although Lavelle et al., only focused on OCB in their model, Spector and Fox (2002) discuss  
4 target-specificity in relation to CWB.  
5  
6

7  
8 Some evidence in the expected direction of the moderating role of Big Five personality  
9 traits, and EI in the relationships between job stressors and positive emotion and negative  
10 emotion emerged. For example, high conscientious, emotionally intelligent, and agreeable  
11 employees who perceived higher levels of role ambiguity, reported higher levels of positive  
12 emotion than those low in conscientiousness, EI and agreeableness. Extraverted and  
13 conscientious employees who perceived high work constraints reported lower levels of negative  
14 emotion than non-extraverted and conscientious employees. Therefore, evidence in support of  
15 moderation suggests that the Big Five personality traits and EI are likely to play an important  
16 role in the emotion regulation process. Conscientious, emotionally stable, extraverted, agreeable,  
17 and emotionally intelligent individuals are likely to make effective use of antecedent-focused  
18 emotion regulation strategies to attain desired affective states. Surprisingly, there was no support  
19 for the predicted moderating role of Openness.

35

### 36 *Limitations*

37  
38 One advantage of this study is the use of other reports of OCB and CWB. In so doing,  
39 certain biases that might distort correlations of the OCB and CWB measures with participant  
40 reports of other variables are likely minimized. However, employees might have chosen co-  
41 workers who would report on their behaviours more favorably and furthermore, co-workers may  
42 only be cognizant of those behaviours that they can actually see (Fox, Spector, Goh, &  
43 Bruursema, 2007).  
44  
45  
46  
47  
48  
49  
50  
51

52  
53 Additionally, as the current study is of a cross-sectional nature, it cannot purport to  
54 provide a causal test of relationships. Therefore, future research should clarify the theorized  
55  
56  
57  
58  
59  
60

1  
2  
3 relationships using longitudinal study designs. Further, testing individual linkages among  
4  
5 variables specified in the model, rather than performing more robust analyses employing  
6  
7 structural equation modelling is another limitation of this study. The sample size achieved in this  
8  
9 study was smaller than the number of parameter estimates in model. In this regard, using a  
10  
11 structural equation modelling methodology would have produced unreliable parameter estimates.  
12  
13  
14

### 15 *Implications for HR*

16  
17 From a practical standpoint, the findings from this study suggest that HRM policies and  
18  
19 practices may have an important role to play in the effective management of emotions in the  
20  
21 workplace, and thus in reducing negative workplace behaviours and increasing positive  
22  
23 workplace behaviours. In particular, our results suggest that HRM practices such as recruitment  
24  
25 and selection and training and development should be more emotion-oriented or focused. For  
26  
27 example, including assessments of EI and theoretically-relevant personality traits in employee  
28  
29 selection systems to select employees with effective emotional regulation tendencies can reduce  
30  
31 negative emotion and CWB and enhance OCB.  
32  
33  
34  
35

36  
37 HR managers should also consider developing and implementing training and  
38  
39 development programs geared towards helping employees engage in more effective emotion  
40  
41 management and emotional regulation processes so that they can cope with the environmental  
42  
43 demands of the workplace. In addition, to be effective in reducing negative emotion and  
44  
45 enhancing positive emotion, the focus of HR managers should also be on creating more positive  
46  
47 and supportive work environments through HRM policies and practices. Here, the key is not the  
48  
49 policies and practices per se, but employees' perceptions of how managers implement and lead  
50  
51 such policies and practices (Knies & Leisink, 2014). Specifically, practices perceived to enhance  
52  
53 employee well-being (commitment-focused) are more positively received than those perceived as  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 control-focused (e.g. reduce costs and exploiting employees) (Nishii et al, 2008). Moreover, HR  
4  
5 practices have causal effects different from their functional purpose. Those practices viewed by  
6  
7 employees as ‘personalised’ commitment to them by the organisation as well as being effectively  
8  
9 implemented and lead by managers may result in employees exhibiting positive attitudes and  
10  
11 engaging in discretionary behaviours such as OCB and attendance (Purcell & Hutchinson, 2007).  
12  
13 Therefore, the manner in which HR practices are designed and implemented as well as perceived  
14  
15 by employees will determine their influence on employees’ attitudes and behaviours.

Table 3 (continued)

Predictor Variables	Negative Emotion				Positive Emotion				
	Step 1	Step 2	Step 3	Step 4	Step 1	Step 2	Step 3	Step 4	
Gender	.17*	.15*	.16*	.16*	Gender	-.25**	-.25**	-.19**	-.20**
Age	.02	.08	.08	.09	Age	.18*	.17	.13	.12
Tenure	-.15	-.11	-.11	-.10	Tenure	.03	.02	-.00	.00
WC		.50**	.50**	.51**	RC		-.12	-.10	-.10
EXT			-.10	-.11	ES			.34**	.32**
WC x EXT				-.15*	RC x ES				.14*
R <sup>2</sup>	.05	.30	.31	.33	R <sup>2</sup>	.11	.12	.23	.25
R <sup>2</sup> Δ		.25**	.01	.02*	R <sup>2</sup> Δ		.01	.11**	.02**
F	3.72*	20.88**	17.31**	18.96**	F	8.34**	7.12**	11.92**	11.08**

Note. Standardized parameter estimates are shown  
 WC = Work Constraints; RC = Role Conflict; EXT = Extraversion; ES = Emotional Stability  
 \* p < .05      \*\* p < .01

**Table 4.***Summary of Supported and Non Supported Hypotheses*

	<b>Hypotheses</b>	<b>Support for Hypothesis</b>
Hypothesis 1	Negative emotion as mediator between stressors and CWB	Yes
Hypothesis 2	Positive emotion as mediator between stressors and OCB	Yes
Hypothesis 3	Conscientious as moderator between stressors and emotion	Some support
Hypothesis 4	Emotional Stability as moderator between stressors and emotion	Some support
Hypothesis 5	Extraversion as moderator between stressors and emotion	Some support
Hypothesis 6	Openness as moderator between stressors and emotion	No
Hypothesis 7	EI as moderator between stressors and emotion	Some support
