**ARTICLE INFO**

**ABSTRACT**

In this work, four stable dithieno[3,2-b:2',3'-d]thiophene-based π-extented molecules were designed and synthesized via a Pd-catalyzed Sonogashira coupling reaction. The structures of these symmetrical compounds, including dithieno[3,2-b:2',3'-d]thiophene (DTT) as the π-center and various donor (D) groups, were determined on the basis of NMR spectral data, elemental analysis, and X-ray crystallography. The photo-physical properties of the DTT-based derivatives were fully investigated in both solution and solid state. The notable optical features of their solid-state powders showed significant red-shift in comparison with the luminescence of their dilute dichloromethane solutions. These results combined with the theoretical calculations indicate that they are promising candidates for the several applications in electronic and optoelectronic devices, as well as organic dyes for solar cells.

**1. Introduction**

Considerable attention has been paid to the development of oligothiophenes for use in organic solar cells, 1-2 π-conjugated conducting polymers, 3-6 high-performance organic field-effect transistors (OFET), 7-8 and organic light-emitting materials. 9-16 Generally, one of the strategies for fine-tuning the HOMO-LUMO gap involves the utilization of extended thiophene subunits and particularly those rigid structures possessing an extended π-conjugation in the ground state, 17 such as thienothiophenes (TTs) and dithienothiophenes (DTTs). Thiophenes can be obtained from thienoacenes that are effective for increasing the intermolecular interactions and adjusting the band gap of organic materials in the solid state. 9-16

Dithieno[3,2-b:2',3'-d]thiophene (DTT) contains three annulated thiophene rings and is one of the six isomers of DTTs (dithieno[3,2-b:2',3'-d]thiophene, dithieno[3,4-b:3',4'-d]thiophene, dithieno[2,3-b:2',3'-d]thiophene, dithieno[2,3-b:3',2'-d]thiophene, dithieno[3,4-b:3',2'-d]thiophene, and dithieno[3,4-b:2',3'-d]thiophene) which have unique electronic properties due to their planar, conjugated, sulfur-rich, and highly thermally stable structure. 9,17-19 The first synthesis and spectroscopic assignments of DTT were reported in 1971. 20 The fused structure of DTT can promote π-stacking which is predicted to be a favourable motif for high charge transport in devices. 21-23 This approach can help to create materials with low-energy electronic transitions based on donor-acceptor interactions. 24-26 In this context, Kim and Navarette designed and synthesized a series of D-π-D and D-π-A type molecules base on the DTT unit for nonlinear optical materials. 27-28 They also provided some desirable strategies to access further materials with this type of motif. 29-31 This goal can be achieved by extending the degree of π conjugation within the materials, which affords smaller band gaps. Thus, there is substantial interest in the synthesis and photophysical properties of new families of planar structures with π-conjugated pure-blue light-emitting molecules. Specifically, 6-bis(arylethynyl) substituted DTT derivatives are of interest. In these compounds, the π-functionalized phenylacetylene groups were successfully introduced into the thiophene core at the 2,6-positions to afford planar conjugated structures by employing a modified Sonogashira coupling reaction. The introduction of the phenylacetylene groups is expected to extend the conjugation of the thiophene chromophore. This results in a shift of the wavelength of absorption and fluorescence emission into the pure blue visible region of the electromagnetic spectrum.

and an improvement of the fluorescence quantum yields. In this paper, we report the synthesis of four types of dithienothiophene derivatives that combine the high hole mobility function of diarylethynyl substituents with the high efficiency and hole-injection ability of dithienothiophene as the conjugation core.

This was achieved by using a Pd-catalysed Sonogashira coupling reaction (Scheme 1). In addition, the synthesis of four D-π-D chromophores 2 starting from dithieno[3,2-b:2',3'-d]thiophene is also described. Moreover, the photo-physical properties of these compounds are examined in solution through spectroscopic techniques, and this is supported with density functional theory (DFT) calculations.

2. Results and discussion

2.1. Synthesis and characterization

2,6-Dibromodithieno[3,2-b:2',3'-d]thiophene 1 was prepared by brominating dithieno[3,2-b:2',3'-d]thiophene (DTT) with N-bromosuccinimide (NBS) in acetic acid at room temperature for 2 h according to the previously reported procedure. The Pd-catalysed Sonogashira cross-coupling reactions were carried out between the 2,6-dibromodithieno[3,2-b:2',3'-d]thiophene 1 and the phenylacetylenes under the modified reaction conditions to afford the target 2,6-bis(arylethynyl)-substituted dithieno[3,2-b:2',3'-d]thiophenes 2a–d in moderate yield. (Scheme 1).

The structures of these novel planar π-conjugated compounds 2a–d were fully characterized on the basis of 1H-NMR, 13C-NMR spectra (see Figure S1–8 in the Supporting Information). Simultaneously, the structures of 2a–d were further established on the basis of the base peak molecular ion at m/z [M+] 369.00 for 2a, 508.11 for 2b, 456.04 for 2c and 482.13 for 2d in their mass spectra. All results were consistent with the proposed structures. These four bis(arylethynyl)-functionalized dithieno[3,2-b:2',3'-d]thiophenes 2a–d are very stable solids with colours from orange to red that can be kept in air for prolonged periods of time at room temperature. All π-extended molecules are noteworthy for its good solubility in organic solvents.

A single crystal of 2c, suitable for X-ray diffraction studies, was obtained by slow evaporation of solvents from a mixture of CH2Cl2 and hexane (3:2) at room temperature. From the X-ray diffraction studies, the extended π-conjugation of the dithieno[3,2-b:2',3'-d]thiophene derivative 2c (Figure 1a) was revealed which lies on a mirror plane. From the packing pattern, a supramolecular network was constructed via a number of complicated intermolecular interactions. As a representative example, there are S1· · · S2 i interactions at 3.408 Å giving rise to chains parallel to the c axis (Figure 1b). These chains then stack parallel to the b axis, and no significant π-π stacking interactions between the pyrene rings were observed. However, there are two different kinds of interactions based on the planar π-conjugated thiophene and C=O aromatic ring, namely: 1) C–H···π interaction of the donor group with the C=O aromatic ring (blue plane), where the C–H···π distance is 2.704 Å; and 2) an S···π interaction of the S atom with the thiophene ring of the neighbouring molecules (dark blue plane) at a distance of 3.241 Å (Figure 1c). These intermolecular interactions increase the effective dimensionality of the electronic structure and are beneficial to charge transport (Figure 1d). The DTT core adopt planar conformation, and the mean tilt angle between the two molecular planes is 43.3°. Interestingly, 2,6-distyryldithieno[3,2-b:2',3'-d]thiophene, which feature a trans–configuration between the double bonds, possesses a mean tilt angle of 37.1°. Consequently, it is beneficial to efficiently reducing π-π interactions and aggregation-caused quenching with the increasing of the tilt angle. This suggest these chromophores can be as good candidates of the phosphorescent organic light-emitting diodes.

2.2. Photo-physical properties

The UV-vis absorption and fluorescence spectra of these four types of 2,6-bis(arylethynyl)-substituted dithieno[3,2-b:2',3'-d]thiophenes 2a–d were measured in dilute dichloromethane and the optical data is summarized in Table 1. Compared with the value for the parent compound DTT at 291 nm, the maximum absorption wavelength of the D-π-D DTT derivatives 2 is observed more than ca. 95 nm red-shifted to 386 (2a), 390 (2b), 392 (2c), and 415 (2d). As expected, the molecular geometries of the D-π-D structures have an impact on the optical properties primarily due to intramolecular charge transfer (ICT). On the other hand, for the UV/vis absorption spectra of 2a–c, the profiles of these spectra are almost identical and the absorption bands are observed in the range 340–430 nm (Figure 2a), which exhibited a large number of transition bands.

The fluorescence spectra of 2a–e exhibited a sharp peak at λem max = 421, 424, and 429 nm with a shoulder, respectively. The emission spectrum of 2d displays a single broad peak at 484 nm, which indicates that the emission occurs from the lowest excited state with the largest oscillator strength. With the increasing the π-conjugation,
a gradual bathochromic shift in the $\lambda_{\text{em\ max}}$ is clearly observed in the order $2a < 2b ≈ 2c < 2d$, implying that the energy gap between the ground and the excited states decreases in this order. In this process, the ICT plays an important role in lowering the energy gap.\(^{42–45}\) The quantum yields ($\Phi = 0.41$ to $\Phi = 0.57$) of the compounds show higher than compound $1$ ($\Phi = 0.01$) with the electron-donating ability of the functional group para to the benzene. We also find that there are slight differences, in this process, this was thought to be the ICT plays an important role in lowering the energy gap.

Synchronously, we also obtained the UV-Vis absorption spectra and emission spectra of $2a$-$d$ in thin neat films (see Figure S9 in the Supporting Information), and the corresponding data are summarized in Table 1. We noted that the four DTT-based molecules displayed slight bathochromic and hypsochromic shift. Interestingly, those phenomena, and displayed compounds as films exhibited significant bathochromic shift and the concentration effect in dichloromethane at room temperature.

\(\Delta \mu\) in thin neat films (see Figure S9 in the Supporting Information), and the corresponding data are summarized in Table 1. We noted that the four DTT-based molecules displayed slight bathochromic and hypsochromic shift. Interestingly, those compounds as films exhibited significant bathochromic phenomena, and displayed $\lambda_{\text{film\ max}}$ Values of 541 nm, 498 nm, 537 nm, and 539 nm, respectively, and compared with their corresponding emission spectra in solution, and red-shift range is 55–120 nm (120 nm for $2a$, 74 nm for $2b$, 108 nm for $2c$, and 55 nm for $2d$, respectively). These results are probably due to the planar π-conjugation structures that tend to form dimers.

The concentration dependent fluorescent measurement of compounds $2$ were investigated, and the emission intensity increased with the increasing of the solutions. Figure 3 shows the fluorescence emission spectra of compound $2b$ and the concentration effect in dichloromethane at room temperature. On increasing the concentration of $2b$ from $1.0 \times 10^{-8}$ M (line 1) to $1.0 \times 10^{-4}$ M (line 9), the corresponding emission at 429 nm was observed for the monomer unit, and the intensity of this emission band gradually increased. The reason is likely associated with the sterically hindered substituents (the two bulky tert-butyl groups) at the 2,6-positions in $2b$ which play an important role for inhibiting the close face-to-face stacking interaction between the neighbouring DTT units; this is consistent with the crystallographic results for $2c$.

In order to obtain more insight into the photo-physical properties of these new coplanar-shaped conjugation compounds, the normalized absorption spectra and the emission spectra of compound $2$ in various solvent systems were determined, and all of the compounds exhibited almost identical regular changes. So we summarized the optical data of $2d$ in Table 2 as a representative. It is well-known that solvatochromic effects not only depend on molecular structure, but also depend on the nature of the chromophore, as well as the solvents.\(^{46}\) Each monomer exhibited slight solvatochromism in the absorption spectra and emission spectra. For $2d$, a change of solvent from nonpolar cyclohexane to polar DMF caused only a very slight (positive) bathochromic shift with the π-π* absorption band moving from 410 to 415 nm. On the other hand, in the case of the emission spectra of $2d$, we observed a substantial positive bathochromic shift with a peak at around 446 nm in cyclohexane, whilst a broad and red-shifted emission with only one peak at 515 nm was observed in the highly polar solvent DMF (Figure 4). Such large Stokes’ shift observed for $2d$ in polar solvents may result from the difference of the dipole moments between the delocalized ground state and the highly localized excited state. The highly localized excited state must arise from the intramolecular charge transfer (ICT) between the NMe$_2$ group and the thiophene core.\(^{47–49}\) The relationship between the Stokes’ shift and the difference in the dipole moments can be related by the Lippert–Mataga equation:

\[
\Delta v = 2\Delta\mu\text{eg}/hca^2 + \text{const},
\]

\[
\Delta f = \left(\epsilon - \epsilon_0\right)/(2\epsilon + 1) - [(n^2 - 1)/(2n^2 + 1)]
\]

where $\Delta v$ and $\Delta f$, are Stokes’ shift and the difference in the dipole moment between the excited and ground states, respectively; $\epsilon$ is the orientation polarizability; $\hbar$ is Planck’s constant; $\epsilon$ is the velocity of light; $a$ is the Onsager radius around a fluorophore; $\epsilon_0$ is the dielectric constant; $n$ is refractive index.\(^{31,35}\) To calculate $\Delta\mu$ and the Stokes’ shifts for $2d$ were plotted against the $\Delta f$ values in the solvents 1,4-dioxane, cyclohexane, THF,
Figure 4. (a), (b) Normalized fluorescence spectra and Lippert-Mataga plots of compound 2d recorded in (A) 1, 4-dioxane, (B) Cyclohexane, (C) THF, (D) CH2Cl2, and (E) DMF at 25 °C.

\[a\]All measurements were performed under degassed conditions.

According to the Lippert–Mataga equation, the $\Delta \mu_{eg}$ value for 2d was estimated to be ca. 30 D (from the slope), meaning that the dipole moment of 2d drastically changed from the ground to the excited states. On the basis of the large $\Delta \mu_{eg}$ value and the DFT analysis for the ground states, one might suppose that charge separation can exist only in the excited states of the donor-modified 2d. The thiophene core in 2d can behave as an acceptor moiety against the dimethylamino groups to increase the fluorescence solvatochromicity probability based on the ICT mechanism. As expected, the findings obtained from UV/vis and fluorescence spectra and Lippert–Mataga analysis imply that the charge separation arises in the excited states of the donor-modified 2d.

2.3. Quantum chemistry calculations

To reinforce the ICT mechanism, DFT calculations for 2 were performed to understand the electronic structures of the D-π-D compounds at the B3LYP/6-31G+(d) level. In particular, the effect of the introduction of donor moieties onto the π-extended DTT. The optimized molecular geometries and frontier molecular orbitals of the four DTT-based derivatives for the DTT core are illustrated in Figure 5. In this model, the HOMOs of the compounds 2 are almost spread over the entire molecular skeleton, while the LUMOs are mostly distributed over the π-center, including the DTT core and the side triple bonds onto the DTT unit. Compared with the DTT unit, the separated LUMOs resulted from the electron-donating nature of the phenyl groups. The gradually increasing HOMO energy levels were delocalized onto the backbone, implying that the electrons were delocalized by the introduction of the conjugated side chain. The resulting extension of the side chain conjugation decreased the bandgap of the DTT derivatives resulting in the improved absorption of light at longer wavelengths, consistent with the photo-physical properties results.

3. Conclusion

In this work, we designed and synthesized four symmetric D-π-D type molecules via Sonogashira coupling reaction with DTT and various kinds of p-substituted phenylacetylenes under mild reaction conditions. Those DTT-based derivatives 2, with planar π-extended conjugated structures were fully characterized. The HOMO–LUMO gap was diminished by an increase in the HOMO energy levels and decrease in the LUMO energy levels, which led to remarkable intermolecular charge-transfer (ICT). The results were verified through inspecting the absorption and emission spectra of compounds 2, for which obvious red-shifts were observed both in the solutions and in the solid state. Given these results, these compounds are promising as blue organic light-emitting materials for the fabrication of OLED devices. Moreover, the D-π-D organic molecules with sufficient conjugation to form a delocalized HOMO of suitable energy level for a p-type organic semiconductor, as well as solar cell. And further detailed investigations aimed at developing this applied research is ongoing in our group.
4. Experimental section

1H /13C NMR spectra were recorded at 300 MHz and 75 MHz on a Nippon Denshi JEOL FT-300 NMR spectrometer in deuteriochloroform with Me4Si as an internal reference. Mass spectra were obtained on a Nippon Denshi JMS-HX110A Ultrahigh Performance Mass Spectrometer at 75 eV using a direct-inlet system. Elemental analyses were performed by Yanaco MT-5. UV-vis spectra were recorded on a Perkin Elmer Lambda 19 UV/VIS/NIR spectrometer. Emission spectra were performed in a semimicro fluorescence cell (Hellma®, 104F-QS, 10 × 4 mm, 1400 μL) with a Varian Cary Eclipse spectrophotometer. Gas–liquid–chromatograph (GLC) analyses were performed by Shimadzu gas chromatograph, GC-14A; silicone OV-1, 2 m programmed temperature rise, 12 °C min⁻¹; carrier gas nitrogen, 25 mL min⁻¹.

4.1. Synthesis of 2,6-bis(phenylethynyl)dithieno[3,2-b:2′,3′-d]thiophene (2a)

2,6-Dibromodithieno[3,2-b:2′,3′-d]thiophene ([1] 150 mg, 0.424 mmol, phenylecylcine (0.15 mL, 1.37 mmol), Pd(PPh₃)₄ (30 mg, 0.043 mmol), PPh₃ (22.3 mg, 0.086 mmol), Et₃N (7.5 mL), Cul (20 mg, 0.106 mmol) and DMF (7.5 ml) were mixed together and heated at 100 °C for 78 h in a Schlenk tube equipped with a magnetic stirring bar and a reflux condenser under N₂ atmosphere. The reaction was quenched with saturated solution of ammonium chloride (30 mL) and extracted with CHCl₃ (100 mL) three times. Then, the combined organic phase was washed with brine, and dried over MgSO₄. Evaporation of the solvent under vacuum resulted in a solid residue. The residue was added in silicone gel (Wako gel, C-300) and purified by column chromatography using hexane as eluent and recrystallization from hexane afforded the desired compound 2a as yellow prisms (44 mg, 24%); m.p. 153 °C; δ₁H (CDCl₃) 1.33 (18H, s, tert-butyl), 7.36 (2H, s, Ar-H) and 7.41 (4H, d, J = 8.8 Hz, Ar-H); δ₁C (CDCl₃) 29.71, 124.01, 132.73 and 150.39; MS: m/z: 369.00 [M⁺]. C₂₆H₁₆S₃ (369.55): Anal. C calcd for C 72.69, H 3.05; Found C 72.41, H 3.08.

4.2. Synthesis of 2,6-bis(4-tert-butylphenylethynyl)dithieno[3,2-b:2′,3′-d]thiophene (2b)

Similarly, 2,6-bis(4-tert-butylphenylethynyl)dithieno[3,2-b:2′,3′-d]thiophene (2b) was obtained in 20% yield as yellow needles (hexane); m.p. 187 °C; δ₁H (CDCl₃) 1.33 (18H, s, t-Bu), 7.39 (4H, d, J = 8.4 Hz, Ar-H), 7.43 (2H, s, Ar-H) and 7.48 (4H, d, J = 8.4 Hz, Ar-H); δ₁C (CDCl₃) 29.71, 40.17, 109.16, 111.81, 124.01, 132.73 and 150.4; MS: m/z: 508.11 [M⁺]. C₃₂H₂₁S₄ (508.76): Anal. Caled for C 76.29, H 4.95; Found C 76.02, H 4.35.

4.3. Synthesis of 2,6-bis(4-methoxyphenylethynyl)dithieno[3,2-b:2′,3′-d]thiophene (2c)

Similarly, 2,6-bis(4-methoxyphenylethynyl)dithieno[3,2-b:2′,3′-d]thiophene (2c) was obtained in 18% yield as yellow needles (hexane); m.p. 157 °C; δ₁H (CDCl₃) 3.84 (6H, s, OMe), 6.90 (4H, d, J = 8.8 Hz, Ar-H), 7.41 (2H, s, Ar-H) and 7.48 (4H, d, J = 8.8 Hz, Ar-H); δ₁C (CDCl₃) 55.35, 81.83, 95.04, 114.16, 114.64, 124.58, 124.67, 131.09, 133.05, 141.50 and 160.05; MS: m/z: 456.04 [M⁺]. C₂₆H₂₃S₃ (456.60): Anal. Caled for C 68.39, H 3.53; Found C 68.14, H 3.54.

4.4. Synthesis of 2,6-bis[(4-dimethylamino)phenylethynyl]dithieno[3,2-b:2′,3′-d]thiophene (2d)

Similarly, 2,6-bis[(4-dimethylamino)phenylethynyl]dithieno[3,2-b:2′,3′-d]thiophene (2d) was obtained in 5% yield as reddish-brown prisms (CHCl₃); m.p. 255 °C; δ₁H (CDCl₃) 3.01 (12H, s, Me), 6.67 (4H, d, J = 8.8 Hz, Ar-H), 7.36 (2H, s, Ar-H) and 7.41 (4H, d, J = 8.8 Hz, Ar-H); δ₁C (CDCl₃) 29.71, 40.17, 109.16, 111.81, 124.01, 132.73 and 150.39; MS: m/z: 482.13 [M⁺]. C₂₆H₂₃S₄ (482.69): Anal. Caled for C 69.67, H 4.59, N 5.80; Found C 69.54, H 4.54, N 5.72.

4.5. Single-crystal X-ray diffraction measurements

A suitable single crystal (0.96 × 0.24 × 0.03 mm³) was mounted on a Bruker APEX 2 CCD diffractometer equipped with fine-focus MoKα (λ = 0.71073 Å) sealed tube radiation source for 2c. Detailed crystallographic data for 2c: C₂₆H₁₆O₂S₃, M = 456.57, orthorhombic, Pmca₂₁, a = 50.008(18), b = 7.318(3), c = 5.954(2) A, V = 2178.9 (14) Å³, Z = 4, Dₐ = 1.392 g/cm³, T = 150(2) K, yellow lath; 9611 reflections measured of which 2715 were independent; data corrected for absorption on the basis of symmetry equivalent and repeated data (min and max transmission factors: 0.723 and 0.989) and Lp effects, R_int = 0.042, structure solved by direct methods, F² refinement. R = 0.032 for 2360 data with F² > 2σ(F²), wR² = 0.078 for all data, 174 parameters. CCDC 1497723 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Acknowledgments

This work was performed under the Cooperative Research Program of “Network Joint Research Center for Materials and Devices (Institute for Materials Chemistry and Engineering, Kyushu University)”. We would like to thank the OTEC at Saga University and the International Cooperation Projects of Guizhou Province (No. 20137002), The Royal Society of Chemistry for financial support and the EPSRC is thanked for an overseas travel grant to C.R.

Supplementary data

Electronic Supplementary Information (ESI) available: Details of single-crystal X-ray crystallographic data. 1H, 13C NMR of 2, and Cartesian coordinates of all optimized structures for originality of the computation results. For ESI and other electronic format see DOI: 10.1039/x0xx00000x
