Abstract: A planetary gearbox model comprising five spur gears (sun, ring and three planets) and the carrier, has been developed and analyzed. The influence of gear teeth backlash and friction during mixed regime of lubrication have been taken into consideration. Greenwood and Tripp model is employed while viscous friction is calculated analytically using the functions of Evans and Johnson. A combined tribodynamics modeling approach has been implemented and modal analysis is performed in order to predict the coupled mechanism of tribological and dynamic behavior, subjected to backlash and excited at the gear meshing frequency. The software used for the simulations is ADAMS MSc (Student Edition), where the model variables (concerning gear geometry and forcing functions) have been added in a parametric way. The results showed that small variations of the Dynamic Transmission Error (DTE) affect notably the viscous friction through changing the contact load between the engaged teeth pairs. Also, higher values of the Strubeck oil parameter due to higher film thickness or lower surface roughness in the mixed lubrication regime lead to reduction of the boundary friction, whereas a reduction of the total generated friction occurs when increasing the angular velocity of the input gear body (due to higher film thickness and smaller asperity interactions). The above are leading to reduced power loss of the mechanism. Finally, a characterization of the system dynamics is presented using the calculated eigenvalues and eigenmodes of the corresponding linearised system. Potential interactions with the gear meshing frequency of the system are also examined.

Keywords: planetary gearbox, teeth backlash, boundary and viscous friction, Dynamic Transmission Error, mixed lubrication regime
1. Introduction

Gears are widely used machine elements in power transmission applications, characterized by high efficiency. However, they can be subjected to severe operating conditions giving rise to aggressive dynamics. Planetary gears are rather compact mechanisms, excellent for transmitting significant power with large speed reductions (or amplifications). Such mechanisms are used in many applications (e.g. wind turbines, aircraft engines, hybrid car transmissions) because of their large bearing capacity, high reliability and long life-span.

In the work of Bartelmus [1] computer simulations revealed that conditions similar to those occurring at resonance may lead to damage of teeth flanks during the service life of a gearbox system. The time varying teeth meshing stiffness and backlash, which influence the dynamic behaviour of the gearbox, are the main excitation parameters in the model of Łuczko [2], who studied the chaotic vibrations in a single stage spur gear transmission. The dynamics of a back-to-back planetary gear, experimental and numerical modal analysis techniques were investigated by Hammami et.al [3]. The gear teeth backlash is considered as one of the main nonlinearities and it may cause oscillations and inaccuracy, leading to poor performance of control systems in many applications [4-6]. Therefore, the dynamic modeling and performance analysis of planetary gear transmissions with backlash have attracted much attention.

Z. M. Sun [7] established a nonlinear dynamic model of a planetary gear transmission considering backlash and mesh stiffness. M. Hamed [8] presented a mathematical model, where the dynamic transmission error was used to analyze the influence of nonlinear oscillations of spur gear pairs with backlash on planetary gear pairs. Q. L. Huang [9] built an optimized mathematical model of a gear transmission system on the basis of a nonlinear purely rotational dynamic model of a multistage closed-form planetary gear, aiming at minimizing the vibration displacement of the low-speed carrier. A lumped parameter nonlinear torsional vibration model of a single-stage planetary set is proposed by Shyyab and Kahraman [10]. It includes all possible power flow configurations, variation of number of planets in any spacing arrangement and planet mesh phasing configuration.

was shown that uniform load distribution on gear flank leads to longer life of the mechanism. The software gives complete product information in the early phase of product life cycle (PLC). Mohammadpour et al. [14] presented a tribo-dynamic model for planetary gear sets of Hybrid-Electric-Vehicle configurations. Their model comprises a 6 degree-of-freedom torsional multi-body dynamic system, as well as a tribological contact model in order to evaluate the lubricant film thickness, friction and efficiency of the meshing gear teeth contacts. A model to simulate the dynamic behaviour of a single-stage planetary gear train with helical gears was developed by Kahraman [15]. His three-dimensional dynamic model includes all six rigid body motions of the gears and the carrier of the planetary mechanism.

In this paper, a planetary gearbox, which includes five spur gears (sun, ring and three planets) and the carrier, is modeled in ADAMS environment. A combined tribodynamics modelling approach has been implemented and modal analysis is performed in order to predict the coupled mechanism of tribological and dynamic behaviour (subjected by backlash and excited at the gear meshing frequency). The results show that a small variation of the DTE affects notably the viscous friction through changing the contact load between the engaged teeth pair.

2. The mechanical system

The studied planetary gearbox comprises the sun (external spur gear), three planets (external spur gears), one carrier (plate) and one ring (internal spur gear). The gearbox stick diagram is presented in figure 1.

The power can be provided either from the sun-gear (input A) or the carrier (input B) or the combination of those two (inputs A & B). The power is transmitted through the planets and the carrier to the ring-gear, which is the output of the gearbox. In order to maintain kinematic equilibrium, the following equations relating the angular velocity of the bodies (\(\omega\)) and the number of gear teeth (\(N\)) have to be fulfilled:

\[
(N_r + N_s) \cdot \omega_c = \omega_r \cdot N_r + \omega_s \cdot N_s
\]

(1a)

\[
\frac{\omega_c}{\omega_r} = \frac{N_r}{N_s}
\]

(1b)

\[
\omega_r = \omega_s / \left(\frac{N_r}{N_s} + 1\right)
\]

(1c)

\[
\omega_p = \omega_r \cdot N_r / N_p
\]

(1d)

The fundamental meshing frequency is given as
During the operation of the mechanism, friction forces and backlash take-up seem to increase vibration and noise, leading to reduction of gearbox efficiency. Generally, the reactions applied on each gear could be classified as:

- external (e.g. the input torque)
- moment of inertia (because of the angular velocity variation of each gear body)
- internal friction torque (between the gear pairs)
- dynamic transmission torque (DTE) induced torque

### 3. Teeth Backlash

Constructional inaccuracy, intentional shape of the gear involute, as well as gear tooth wear are the reasons behind backlash. As the two gears are in mesh, there is a gap between the teeth surfaces in the meshing zone which contributes to non-linear effects in the system vibrations and noise. The DTE is often used as an indicative variable for predicting the system’s vibration and noise. The mathematical expression of the DTE, which relates the angular displacement ($\theta$), and the rate of change $\dot{DTE}$, is presented below:

\[
DTE_{12} = fa \cdot (\theta_1 \cdot r_1 - \theta_2 \cdot r_2) \\
DTE_{12} = fa \cdot (\dot{\theta}_1 \cdot r_1 - \dot{\theta}_2 \cdot r_2)
\]

The system non-linearity because of the backlash can be expressed by piecewise linear equations where DTE is compared each time with the backlash value (B). The result of this comparison defines the value of $fa$ regulatory factor, which nullifies or not the corresponding torque.

When tooth meshing surfaces are in contact, the stiffness and damping forces are applied and their value depends on the type of contact (single or double teeth pairs), according to a specific frequency of alternation, as shown in Fig. 4. So, backlash reset torques for each gear could be presented as in Fig. 5:

\[
\text{wheel 1: } \cos \varphi \cdot r_1 \cdot (DTE_{12} \cdot k_{T12} + \dot{DTE}_{12} \cdot c_{T12}) \\
\text{wheel 2: } \cos \varphi \cdot r_2 \cdot (DTE_{12} \cdot k_{T12} + \dot{DTE}_{12} \cdot c_{T12})
\]
These forces are applied on the line of action of the gear-pair and that is why $\cos \varphi$ (gear pressure angle) is part of each body’s equation. During teeth meshing, hysteretic material damping needs to be included [14]. The damping coefficient for the contact of a single meshing teeth pair can be obtained as $c=0.009k/f_m$, where $f_m$ is the meshing frequency. In order to obtain the total damping variation during meshing, a similar approach to the above equation is considered.

4. Gear Teeth Friction

During the operation of the planetary system, two kinds of friction are expected to be present: boundary ($T_b$) and viscous ($T_v$). The total friction is then calculated for each gear-pair and it is assigned to each body [14]:

$$T_{FR} = T_b + T_v$$  \hspace{1cm} (6)

4.1 Boundary Friction

Boundary friction forces are developed because of the asperity interaction of the boundary surfaces and are calculated using the Greenwood and Tripp (1970) model [11]. Contact problems between rough surfaces have been studied by many researchers. It is known that in real life scenarios, the surfaces that are in contact are always rough. The first attempt was in 1966 by Greenwood and Williamson [16] for elastic rough surface contacts, assuming that rough surface asperities deform elastically. In reality, if the material’s yield strength is exceeded, elasto-plastic deformations occur. The latter scenario was investigated later. The Greenwood and Williamson [16] model assumes Gaussian distribution for asperity summits and the contact of two rough surfaces is considered as that of a rough surface that deforms elastically and a flat surface that is rigid. In the model, the asperities have the same radius for simplicity and the summits follow a Gaussian (height) distribution. Greenwood and Tripp [11] applies the contact model for two rough surfaces.

Continuous efforts of researchers have expanded the study of the basic assumptions of Greenwood and Williamson [11, 16-18] and new methods have been proposed, such as fractal theory, numerical methods etc. [19-20]. In this work the authors are using the expanded model of Greenwood and Williamson extended by Greenwood and Tripp for line contacts.
According to this model, the friction force for the boundary surfaces $f_b$ can be expressed as:

$$f_b = \tau_L \cdot A_a$$  \hspace{1cm} (7)

As it concerns the lubricant shear stress $\tau_L$:

$$\tau_L = \tau_O + \varepsilon \cdot P_m$$  \hspace{1cm} (8)

where $P_m = \frac{W_a}{A_a}$  \hspace{1cm} (9)

In order to calculate $A_a$ (asperity contact area) and $W_a$ (share of the contact load carried by the asperities), the statistical functions $F_2$, $F_{5/2}$ are used. These are polynomial functions of the Stribeck oil parameter (see Appendix) to estimate the distribution of asperity heights:

$$A_a = \pi^2 \cdot (\xi \cdot \beta \cdot \sigma)^2 \cdot A \cdot F_2(\lambda)$$  \hspace{1cm} (10)

$$W_a = \frac{16\sqrt{2}}{15} \cdot \pi \cdot (\xi \cdot \beta \cdot \sigma)^2 \cdot \sqrt{\frac{\sigma}{\beta}} \cdot \hat{E} \cdot A \cdot F_{5/2}(\lambda)$$  \hspace{1cm} (11)

The Stribeck oil parameter ($\lambda$) is defined as the ratio of the lubricant film thickness ($h$) to the surface roughness ($\sigma$), $\lambda = \frac{h}{\sigma} \leq 3$. The different values of Stribeck oil parameter ($\lambda$ less than 3) studied are in the range proposed of references [1, 2], indicating a mixed regime of lubrication close to boundary regime. Below, in Fig. 6, the typical Stribeck curve is presented, relating the friction coefficient to the Stribeck oil parameter. Three regimes of lubrication are present.

Mechanical components operate under lubricated conditions, where the main function of lubricant is the reduction of both friction and wear of the sliding parts. In most cases, the relationship between friction and lubrication is characterized based on the function $\eta V/W$ (oil viscosity x sliding velocity / normal load, Wakuri et al. [22]) in a curve called Stribeck diagram, reproduced from Bayer [21]. The friction behaviour in the Stribeck diagram is used to explain rubbing phenomena occurring in lubricated contacts. In high values of $\eta U/W$, the friction coefficient is linearly ascending due to fluid film
lubrication; friction is related to viscous forces in the oil film. When load increases or oil viscosity and/or velocity decreases, the $\eta U/W$ factor falls. Then, the fluid film becomes thinner and, consequently, the friction coefficient decreases, up to a minimum value. For even smaller values of $\eta U/W$, the fluid film thickness is further reduced, and metal-to-metal contact starts to occur. Then, the friction coefficient increases as the $\eta U/W$ factor decreases. On the other hand, in the case of two rough surfaces, several authors, such as Hutchings [23]; Bayer [21]; Neale, [24], consider the $\lambda$ value to characterize lubrication in rubbing contacts. This is determined by the relation of oil film thickness (h) and the equivalent surface roughness of both surfaces ($\sigma$). The oil film thickness h can be determined from calculations of the elastohydrodynamic film, such as those described in 1960’s by Dowson et al. [25].

$\lambda$ value has been used to analyze wear and friction responses to a great extent in the literature. However it can be considered somewhat inconsistent by Cann et.al [26], because some microscopic effects, such as the micro-elastohydrodynamic lubrication at the asperities, cannot be explained through $\lambda$ value, because the film thickness becomes smaller than the height of surface asperities and then boundary lubrication takes place.

The simplest method to obtain a Stibbe curve and the method most commonly used, provided one has the appropriate converging gap geometry, is to keep two variables fixed (e.g., load and viscosity) and vary the third (e.g., velocity) over a suitable range so that the contact interface goes through the region of asperity contact (boundary), as well as full fluid-film separation (hydrodynamic). In this work the examined mechanism is operating in mixed lubrication regime and the $\lambda$ parameter was chosen to present directly the obtained results with the film thickens variation due to backlash.

4.2 Viscous Friction

Viscous friction is a shear force exerted on the teeth surfaces due to the presence of the lubricant film. The analytical experimentally obtained expression of Evans and Johnson (1986) is used, which takes into consideration the influence of generated heat during function [12].

$$f_v = F_{flank} \left( 0.87 \cdot a \cdot \tau_0 + 1.74 \cdot \frac{\tau_0}{\bar{p}} \cdot \ln \left( \frac{1.2}{\tau_0 h} \cdot \left( \frac{2K_0}{1+9.6\zeta} \right)^{1/2} \right) \right)$$

$$\zeta = \frac{4}{\pi} \cdot \frac{K}{h/R(x)} \cdot \left( \frac{\bar{p}}{E' R(x) K' \dot{\rho} c \dot{\psi}} \right)^{1/2}$$
Important variables in this calculation are the flank load and the lubricant film thickness.

\[
F_{flank} = DTE \cdot k_T + D\dot{T}E \cdot C_T \tag{14}
\]

\[
h = 2.5 \cdot R(X) \cdot \left(\frac{\eta_0}{(x-E)^{0.1}}\right)^{0.26} \tag{15}
\]

as per reference [27]

5. Power Loss
While boundary and viscous friction forces are applied on each body of a gear-pair, the power loss is the product of the total friction force with the relative sliding velocity between these two gears.

\[
P = f_{tot} \cdot \Delta V(X) \tag{16}
\]

Thus, the friction torque for the gear is given by:

\[
T = \frac{p}{\omega} \tag{17}
\]

6. Equations of Motion
For the gears of the planetary system, the following equations of motion are obtained:

Sun: \( J_s \cdot \ddot{\theta}_s + \cos \varphi \cdot r_s \cdot \sum_{i=1}^{3} (DTE_{spi} \cdot k_{Tspi} + D\dot{T}E_{spi} \cdot c_{Tspi}) - T_{FRs} = T_s \tag{18} \)

Planet: \( J_{pi} \cdot \ddot{\theta}_{pi} - \cos \varphi \cdot r_{pi} \cdot (DTE_{spi} \cdot k_{Tspi} + D\dot{T}E_{spi} \cdot c_{Tspi}) + \cos \varphi \cdot r_{pi} \cdot (DTE_{pri} \cdot k_{Tpri} + D\dot{T}E_{pri} \cdot c_{Tpri}) - T_{FRpi} = 0 \tag{19} \)

Ring: \( J_r \cdot \ddot{\theta}_r - \cos \varphi \cdot r_r \cdot \sum_{i=1}^{3} (DTE_{pri} \cdot k_{Tpri} + D\dot{T}E_{pri} \cdot c_{Tpri}) - T_{FRr} = -T_r \tag{20} \)

The first term refers to the body’s inertia; the second one is the contribution of the DTE; the third term is the total friction torque that is applied on the body; the sum of those three terms is equal to the external torque that is exercised on each gear. For the sun-gear the external torque is the input torque to the gearbox system. As for the ring, this term
means the resisting torque (the applied load) that is transferred out of the planetary mechanism.

If the carrier is fixed, the DTE equations are as below:

\[
DTE_{sp} = f \alpha \cdot (\theta_s \cdot r_s - \theta_p \cdot r_p) \quad (21)
\]

\[
DTE_{pr} = f \alpha \cdot (\theta_p \cdot r_p - \theta_r \cdot r_r) \quad (22)
\]

7. ADAMS Model

In order to simulate the dynamics of the planetary mechanism, a model has been developed using ADAMS MSC Software (student edition), which allows for dynamic simulations. The constraints and bodies of the model are presented in Table 1:

<table>
<thead>

</table>

The gear forces are calculated analytically with the model variables set in a parametric way. The atmospheric dynamic viscosity of the lubricant is \(0.08 \text{ Pa} \cdot \text{s}\), at about \(70^\circ \text{C}\). The simulations carried out refer to the case that the input of the mechanism is at the sun-gear, while the carrier remains stationary. The basic parameters of the sun, planets and ring are presented in Table 2.

Different values of the backlash (B), Stibbeck oil parameter (\(\lambda\)) and angular velocity (\(\omega\)) in the input body (sun-gear) are leading to interesting case studies. These are the following:
- For $B [m]$: $2.0e - 7$, $2.5e - 7$, $3.0e - 7$, $3.5e - 7$
- For $\lambda [-]$: 1, 1.25, 1.5, 1.75, 2
- For $\omega [rpm]$: 1000, 2000, 3000.

In Table 3 the basic roughness and lubricant parameters are presented.

8. Results and discussion

In this section, the results for different case studies are displayed, followed by representative plots. It is shown how friction (viscous and boundary) and applied body forces, lubricant film thickness and power losses can differ by changing the values of backlash, Stribeck oil parameter and input angular velocity.

8.1 Viscous Friction
As it can be observed from Fig. 7, by increasing the DTE values, the viscous friction between the gear pairs of sun-planet and planet-ring is increasing as well. This can be the result of contact load increase.

8.2 Boundary Friction
In Fig. 8, the friction force that is developed as a function of the Stribeck parameter $\lambda$, is presented. In a mixed lubrication regime, higher Stribeck oil parameter, due to higher film thickness or lower surface roughness, leads to reduction of the boundary friction.

8.3 Applied Body Forces
The tangential, radial, as well as total applied force and torque at the planet-gear body, are shown in the following plots, when the input torque is about 63Nm. It appears that by increasing the input speed and the $\lambda$ coefficient, the forces are also increasing.
8.3 Lubricant Film Thickness
The diagrams of lubricant film thickness variation for each gear-pair with respect to input body rotation velocity, are presented in Fig. 10. As it can be seen, the lubricant film thickness increases as the rotational speed of the input sun gear increases.

8.4 Power Losses
Reduction of the total generated friction seems to occur while increasing the angular velocity of the input gear body (sun). This is caused by higher film thickness and smaller asperity interactions between the engaged teeth pairs. This reduction in friction leads to lower power loss of the mechanism, as shown in Fig.11. The model considers power losses due to friction between the meshing gear teeth and viscous damping of the spinning gear shafts.

9. Eigenvalue problem
The high-power-density design of planetary gear sets combined with their kinematic flexibility in achieving different speed ratios makes planetary gear transmissions often an optimum choice. The eigenproblem of the prescribed system (Figure 1) is solved using the corresponding linearised system.

The dynamic models of the sun - planet, ring - planet and carrier - planet are shown in Figures 12a-c. Each gear or carrier is generally allowed to translate in x, y and z (axial) directions and rotate in \( \rho_x, \rho_y \) and \( \theta \) directions as per [15]. A displacement vector \( q_j \) and a mass matrix \( m_j \), corresponding to \( q \), can be defined for each component \( j \) (j = sun, planet, ring, carrier) as below:

\[
q_j = diag[x_j, y_j, z_j, w_{jx}, w_{jy}, u_j]^T
\]

\[
m_j = diag[m_j, m_j, m_j, I_j/r_j^2, I_j/r_j^2, J_j/r_j^3]
\]

where \( m_j, I_j \) and \( J_j \) are the mass, the diametral and polar mass moments of inertia, respectively and \( w_{jx}, w_{jy} = r_j \rho_{jx}, w_{jy} = r_j \rho_{jy}, u = r_j \theta_j \).

The undamped equations of motion for the twelve degrees of freedom of the sun - planet pair take the following form:
For the ring - planet it is:

\[
\begin{bmatrix}
    m_s & 0 \\
    0 & m_{pl}
\end{bmatrix}
\begin{bmatrix}
    \ddot{\mathbf{q}}_s \\
    \ddot{\mathbf{q}}_{pl}
\end{bmatrix}
+
\begin{bmatrix}
    k_{si} & -k_{si} \\
    -k_{si} & k_{si}
\end{bmatrix}
\begin{bmatrix}
    \dot{\mathbf{q}}_s \\
    \dot{\mathbf{q}}_{pl}
\end{bmatrix}
= \begin{bmatrix}
    \mathbf{f}_s \\
    \mathbf{f}_{pl}
\end{bmatrix}
\]  

(22)

The matrices \(K_{si}\) and \(K_{ri}\) and \(K_{c11i}\) and \(K_{c12i}\) matrices are given by [15]:

\[
K_{si} = K_{sp} =
\begin{bmatrix}
    c^2 \beta c^2 \psi_{si} & -c^2 \beta \cos \psi_{si} \sin \psi_{si} & -c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & -c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & c \beta \cos \psi_{si} s \sin \psi_{si} & -c^2 \beta \sin \psi_{si} \\
    c^2 \beta \cos \psi_{si} s \sin \psi_{si} & c^2 \beta \sin \psi_{si} s \sin \psi_{si} & c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & s^2 \beta \sin \psi_{si} & -c \beta s \beta \\
    c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & -c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & c^2 \beta \cos \psi_{si} s \sin \psi_{si} & c^2 \beta \cos \psi_{si} s \sin \psi_{si} & s \beta \sin \psi_{si} & c \beta s \beta \\
    c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & -c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & -c \beta s \beta \cos \psi_{si} s \sin \psi_{si} & s \beta \sin \psi_{si} & -c \beta s \beta \\
    s \beta \sin \psi_{si} & -s \beta \sin \psi_{si} & s \beta \sin \psi_{si} & -s \beta \sin \psi_{si} & c \beta s \beta & c \beta s \beta \\
    -c \beta s \beta & -c \beta s \beta & c \beta s \beta & c \beta s \beta & s \beta & c \beta s \beta
\end{bmatrix}
\]

(25)

\[
\begin{bmatrix}
    c^2 \beta \cos \psi_{ri} s \sin \psi_{ri} & -c^2 \beta \cos \psi_{ri} s \sin \psi_{ri} & -c \beta s \beta \cos \psi_{ri} s \sin \psi_{ri} & -c \beta s \beta \cos \psi_{ri} s \sin \psi_{ri} & c \beta \cos \psi_{ri} s \sin \psi_{ri} & -c^2 \beta \sin \psi_{ri} \\
    c^2 \beta \sin \psi_{ri} s \sin \psi_{ri} & c^2 \beta \sin \psi_{ri} s \sin \psi_{ri} & c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & s^2 \beta \sin \psi_{ri} & -c \beta s \beta \\
    c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & -c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & c^2 \beta \sin \psi_{ri} s \sin \psi_{ri} & c^2 \beta \sin \psi_{ri} s \sin \psi_{ri} & s \beta \sin \psi_{ri} & c \beta s \beta \\
    c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & -c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & -c \beta s \beta \sin \psi_{ri} s \sin \psi_{ri} & s \beta \sin \psi_{ri} & -c \beta s \beta \\
    s \beta \sin \psi_{ri} & -s \beta \sin \psi_{ri} & s \beta \sin \psi_{ri} & -s \beta \sin \psi_{ri} & c \beta s \beta & c \beta s \beta \\
    -c \beta s \beta & -c \beta s \beta & c \beta s \beta & -c \beta s \beta & s \beta & c \beta s \beta
\end{bmatrix}
\]

(26)
The helix angle $\beta$ is zero (spur gears) and $\psi_{xi} = \psi_i - a_s$, $\psi_{zi} = \psi_i - a_r$, where $a_r$, $a_s$ are the transverse operating pressure gear angles, $s \equiv \sin \beta$, $c \equiv \cos \beta$, $k_{zzj} = \text{diag}[k_{xx}, k_{yy}, k_{zz}, \gamma^2 k_{w_jw_j}, \gamma^2 k_{w_jw_j}, 0]$, $\gamma = r_j / r_p$, $k_{w_jw_j} = \rho_j \rho_j / r_j^2$ and $k_{w_jw_i} = \rho_s \rho_s / r_s^2$. The angular position of the planets has been defined as $90^0$, $-30^0$ and $210^0$.

In this work only the rotational (torsional) degree of freedom ($u = r_j \theta_j$) is considered.

Thus, the equations of motion (22) - (24) are reduced to the following (for free vibrations):

$$
\begin{bmatrix}
-k_{yy} & 0 & 0 & 0 & 0 & 0 \\
0 & -k_{xx} & 0 & 0 & 0 & 0 \\
0 & 0 & -k_{zz} & 0 & 0 & 0 \\
0 & 0 & -k_{zz} \psi_i & -\gamma k_{w_jw_j} & 0 & 0 \\
0 & 0 & k_{zz} s \psi_i & 0 & -\gamma k_{w_jw_j} & 0 \\
-k_{yy} \psi_i & -k_{zz} s \psi_i & 0 & 0 & 0 & 0
\end{bmatrix}
= \mathbf{0}
$$

\hspace{1cm} (27)

$$
\begin{bmatrix}
k_{yy} & 0 & 0 & 0 & 0 & -k_{yy} \psi_i \\
k_{xx} & 0 & 0 & 0 & k_{xx} s \psi_i \\
k_{zz} & k_{zz} \psi_i & -k_{zz} s \psi_i & 0 \\
k_{zz}^2 \psi_i + k_{w_jw_j} & -k_{zz} c \psi_i \psi_i & 0 \\
k_{zz}^2 s \psi_i + k_{w_jw_j} & 0 \\
k_{xx} s^2 \psi_i & k_{xx} c^2 \psi_i
\end{bmatrix}
= \mathbf{0}
$$

\hspace{1cm} (28)

$$
\begin{bmatrix}
j_s & 0 & \ddot{u}_s \\
0 & j_{pl} & \ddot{u}_{pl}
\end{bmatrix}
+ k_{sp}
\begin{bmatrix}
c^2 \beta & -c^2 \beta \\
-c^2 \beta & c^2 \beta
\end{bmatrix}
\begin{bmatrix}
\dot{u}_s \\
\dot{u}_{pl}
\end{bmatrix}
= \mathbf{0}
$$

\hspace{1cm} (29)

$$
\begin{bmatrix}
j_r & 0 & \ddot{u}_r \\
0 & j_{pl} & \ddot{u}_{pl}
\end{bmatrix}
+ k_{rp}
\begin{bmatrix}
c^2 \beta & -c^2 \beta \\
-c^2 \beta & c^2 \beta
\end{bmatrix}
\begin{bmatrix}
\dot{u}_r \\
\dot{u}_{pl}
\end{bmatrix}
= \mathbf{0}
$$

\hspace{1cm} (30)

$$
\begin{bmatrix}
j_e & 0 & \ddot{u}_e \\
0 & j_{pl} & \ddot{u}_{pl}
\end{bmatrix}
+ k_{se} s^2 \psi_j + k_{yy} c^2 \psi_i
\begin{bmatrix}
\dot{u}_e \\
\dot{u}_{pl}
\end{bmatrix}
= \mathbf{0}
$$

\hspace{1cm} (31)
The overall planetary system equations of motion can be written as:

\[ \mathbf{M} \ddot{\mathbf{x}} + \mathbf{K} \mathbf{x} = 0 \]  

\[ (32) \]

Where for the rotational mode of vibration,

\[ \mathbf{M} = \text{diag}[J_s/r_s^2, J_{p1}/r_{p1}^2, J_{p2}/r_{p2}^2, J_{p3}/r_{p3}^2, J_r/r_r^2, J_c/r_c^2] \]  

\[ (33) \]

\[ \mathbf{X} = [\theta_s, \theta_{p1}, \theta_{p2}, \theta_{p3}, \theta_r, \theta_c]^T \]  

\[ (34) \]

\[ \begin{bmatrix} \sum_{i=1}^n k_{ii} & -k_{s1} & -k_{s2} & -k_{s3} & 0 & 0 \\ (k_s + k_r + k_{221})_1 & 0 & 0 & -k_{r1} & k_{121} \\ (k_s + k_r + k_{222})_2 & 0 & -k_{r2} & k_{122} \\ (k_s + k_r + k_{223})_3 & 0 & -k_{r3} & k_{123} \\ \end{bmatrix} \]  

\[ (35) \]

\[ \sum_{i=1}^n k_{ii} = \text{SYMMETrIC} \]

For the time invariant case related the eigenvalue problem can be written as follows, having neglected the gyroscopic terms due to the relatively low carrier rotational speed:

\[ (\mathbf{K} - \mathbf{M} \omega_i^2) \Phi_i \]  

\[ (36) \]

where \( \omega_i \) are the natural frequencies and \( \Phi_i \) are the eigenvectors. The system properties of Table 4 are used in order to solve the eigenproblem.

9.1 Gear meshing frequency (GMF) effects

The gear meshing frequency defined as the rotational velocity of the gear wheel multiplied by the number of gear teeth is one of the main noise features in transmissions. Gear meshing creates oscillations in its meshing frequency because of the transmission error, machining errors, stiffness variation, torque fluctuations etc. Consequently, the
dynamic tooth mesh forces are periodic at the mesh frequency and the calculated response contains integer multiples of the harmonics of the fundamental tooth mesh frequency for the operating speeds considered. This result is consistent with the static transmission error excitation model used in lumped-parameter representations. In planetary gear mechanisms, due to the complicated mechanical structure of power distribution, the gears that transmit power for long periods of time are more susceptible to accumulating tooth wear, resulting in larger transmission errors, reduction of the meshing stiffness, and increase of backlash.

In order to study the modal behaviour of the planetary gear system (table 1 data) under typical operating conditions, the sun speed was taken as 1000rpm and the input torque constant at 63Nm. The meshing frequency is then $f_m = 350\text{Hz}$. During the planetary gear mechanism operation, the mesh stiffness can be mistuned due to manufacturing irregularities. In Figure 13, the variation of the first three natural frequencies of the system is presented. As it can be seen there can be interactions with the meshing frequency that affect the mechanism operation (leading to potential resonances) as $K_{sp}$ is varied between $1.5E3\text{N/m}$ to $1.5E4\text{N/m}$.

As it can be seen in Figure 14, the vibration modes can change drastically as $K_{sp}$ varies. Thus, the above analysis can provide planetary system designers with a tool that calculates accurately the dynamic and tribological interactions between the mating gear wheels in the planetary mechanism. It may also assist the proper selection of the gear design parameters to avoid resonance conditions if errors lead to excitation of the mechanism with frequencies close to the fundamental gear meshing frequency and its harmonics.

**Conclusions**

In this work, a combined tribodynamics modeling approach has been implemented and modal analysis is performed in order to predict the coupled mechanism of tribological and dynamic behavior of a five-spur gear planetary gearbox. Backlash and excitation at the gear meshing frequency have been considered. The tribological and dynamic characteristics of the system have been investigated.

The results showed that:

- A small variation of DTE affects notably the viscous friction
- Higher Striebeck oil parameter leads to reduction of the boundary friction in the mixed lubrication regime
Reduction of the total generated friction seems to occur while increasing the angular velocity of the input gear body. This reduction leads to lower power loss of the mechanism.

Modal analysis is also performed, showing the effects of the meshing frequency on the eigenvectors and the eigenmodes of the mechanism.

The future work should comprise the addition of all the dynamic parameters and degrees of freedom to the numerical model. Since real word applications require higher efficiencies, an extension of the work could be also to improve the model in terms of choosing interactively the input either from the sun, the carrier or their combination. The time variant properties of the system (transmission error and meshing stiffness) and their effects in the gear box response and power losses will be examined in a future investigation.
