Abstract

We consider magnetic geodesic flows of the normal metrics on a class of homogeneous spaces, in particular (co)adjoint orbits of compact Lie groups. We give the proof of the non-commutative integrability of flows and show, in addition, for the case of (co)adjoint orbits, the usual Liouville integrability by means of analytic integrals. We also consider the potential systems on adjoint orbits, which are generalizations of the magnetic spherical pendulum. The complete integrability of such system is proved for an arbitrary adjoint orbit of a compact semisimple Lie group.

Contents

1 Introduction

Let $Q$ be a smooth manifold with a Riemannian metric $g = (g_{ij})$. Consider an arbitrary local coordinate system $x^1, \ldots, x^n$ and pass from velocities $\dot{x}^i$ to momenta $p_j$ by using the standard transformation $p_j = g_{ij}\dot{x}^i$. Then $x^i, p_i$ ($i = 1,\ldots,n$) represent the local coordinate system on the cotangent bundle

$T^*Q$ and the standard symplectic form on $T^*Q$ reads $\omega = \sum dp_i \wedge dx^i$. The corresponding canonical Poisson brackets are given by

$$
\{f, g\}_0 = \sum_{i=1}^{n} \left( \frac{\partial f}{\partial x^i} \frac{\partial g}{\partial p_i} - \frac{\partial f}{\partial p_i} \frac{\partial g}{\partial x^i} \right).
$$

The equations of the geodesic flow have the Hamiltonian form on $(T^*Q, \omega)$:

$$
\frac{df}{dt} = \{f, H\} \quad \iff \quad \frac{dx^i}{dt} = \frac{\partial H}{\partial p_i}, \quad \frac{dp_i}{dt} = -\frac{\partial H}{\partial x^i},
$$

where the Hamiltonian $H$ is

$$
H(x, p) = \frac{1}{2} \sum_{i,j=1}^{n} g^{ij} p_i p_j = \frac{1}{2} \sum_{i,j=1}^{n} g_{ij} \dot{x}^i \dot{x}^j.
$$

Here $g^{ij}$ are the coefficients of the tensor inverse to the metric.

The geodesic flow can be interpreted as the inertial motion of a particle on $Q$ with the kinetic energy given by (1). The motion of the particle under the influence of the additional magnetic field given by a closed 2-form

$$
\Omega = \sum_{1 \leq i < j \leq n} F_{ij}(x) dx^i \wedge dx^j,
$$

is described by the following equations:

$$
\frac{dx^i}{dt} = \frac{\partial H}{\partial p_i}, \quad \frac{dp_i}{dt} = -\frac{\partial H}{\partial x^i} + \sum_{j=1}^{n} F_{ij} \frac{\partial H}{\partial p_j}.
$$

The equations (2) are Hamiltonian with respect to the "twisted" symplectic form $\omega + \rho^* \Omega$, where $\rho : T^*Q \to Q$ is the natural projection. Namely, the new Poisson bracket is given by

$$
\{f, g\} = \{f, g\}_0 + \sum_{i,j=1}^{n} F_{ij} \frac{\partial f}{\partial p_i} \frac{\partial g}{\partial p_j},
$$

and the Hamiltonian equations $\dot{f} = \{f, H\}$ read (2).

The flow (2) is called magnetic geodesic flow on the Riemannian manifold $(Q, g)$ with respect to the magnetic field $\Omega$. For simplicity, we shall refer to (2) as a magnetic Poisson bracket and to $(T^*Q, \omega + \rho^* \Omega)$ as a magnetic cotangent bundle.

**Outline and Results of the Paper.** Our work has been inspired by a recent paper by Efimov [?] in which he proved the non-commutative integrability of magnetic geodesic flows on coadjoint orbits of compact Lie groups. We observed that using the approach developed in [?], [?] one can extend this result to a wider
class of homogeneous spaces and construct, in many cases, complete algebras of commuting integrals. Besides, this technics turned out to be useful in the theory of integrable magnetic potential systems. Such systems on Stiefel and Grassmann manifolds of two-dimensional planes in \( \mathbb{R}^n \) and complex projective spaces were studied in [? , ?].

In Section 2, we recall the concept of non-commutative integrability suggested by Mishchenko and Fomenko [?] and its relation with the Hamiltonian group action established in [?]. In Section 3 we introduce a class of homogeneous spaces \( G/H \) admitting a natural \( G \)-invariant magnetic field. Briefly, this construction can be explained as follows. Let \( G \) be a compact Lie group, \( H \) its closed subgroup and \( \mathfrak{h} \) and \( \mathfrak{g} \) denote the Lie algebras of \( H \) and \( G \), respectively. Suppose that \( a \in \mathfrak{h} \) is \( H \)-adjoint invariant. In particular, \( H \subseteq G_{a} \), where \( G_{a} \subseteq G \) is the \( G \)-adjoint isotropy group of \( a \). Consider the adjoint orbit \( \mathcal{O}(a) \) through \( a \) endowed with the standard Kirillov-Konstant symplectic form \( \Omega_{KK} \) (we can naturally identify adjoint and coadjoint orbits by the use of \( \text{Ad}_G \)-invariant scalar product on \( \mathfrak{g} \)). Then we have the canonical submersion of homogeneous spaces \( \sigma : G/H \rightarrow G/G_{a} \cong \mathcal{O}(a) \) and the closed two-form \( \Omega = \sigma^*\Omega_{KK} \) gives us the required magnetic field on \( G/H \). In particular, for \( H = G_{a} \) we obtain an adjoint orbit with magnetic term being the Kirillov-Konstant form.

We prove the non-commutative integrability of geodesic magnetic flows of the normal metrics (Theorem ??) on \( G/H \) and show, in addition, that for the case of adjoint orbits one can find enough commuting analytic integrals (Theorem ??). The proof is based on recent results concerning geodesic flows on homogeneous spaces [? , ? , ?].

In Section 4, we study the motion of a particle on coadjoint orbits under the influence of an additional potential force field. For the Lie algebra \( \mathfrak{so}(3) \), the system represents the magnetic spherical pendulum. The generalization of the magnetic spherical pendulum to the complex projective spaces is obtained in [?].

In Section 5, we give a representation of the system in the semi-direct product \( \mathfrak{g} \oplus_{\text{ad}} \mathfrak{g} \) and, following the bi-Hamiltonian approach, prove its complete integrability for coadjoint orbits of compact semisimple Lie groups (Corollary ??, Theorem ??). Various aspects of representations of (polarized) coadjoint orbits in semi-direct products as magnetic cotangent bundles are studied in [? , ? , ? , ? , ?].

Let us emphasize that in the present paper we consider integrability as a qualitative phenomenon: the phase space of the system is foliated almost everywhere by isotropic invariant tori with quasiperiodic dynamics. Sometimes this property is not the same as the classical integrability, i.e., existence of explicit formulae for solutions. The simplest example that demonstrates the difference between two types of integrability is the magnetic geodesic flow on a compact constant negative curvature surface. We can represent the geodesics explicitly as projections of magnetic lines from the hyperbolic 2-plane (lines of constant geodesic curvature), but the restriction of the flow onto energy levels \( H > h_{cr} \) are Anosov flows, while the restriction onto energy levels \( H < h_{cr} \) are analytically integrable, where \( h_{cr} \) is some critical level of energy (e.g., see [? , ?]).
2 Integrable Systems Related to Hamiltonian Actions

There are a lot of examples of integrable Hamiltonian systems with $n$ degrees of freedom that admit more than $n$ (noncommuting) integrals. Then, under some assumptions, the $n$ dimensional Lagrangian tori are foliated by lower dimensional isotropic tori. This happens in the case of the so-called non-commutative integrability studied by Nekhoroshev [?] and Mishchenko and Fomenko [?] (see also [?, ?]).

Let $M$ be a Poisson manifold and $\mathcal{F}$ be a Poisson subalgebra of $C^\infty(M)$. Suppose that in the neighborhood of a generic point $x$ we can find exactly $l$ independent functions $f_1, \ldots, f_l \in \mathcal{F}$ and the corank of the matrix $\{f_i, f_j\}$ is equal to some constant $r$. Then numbers $l$ and $r$ are called differential dimension and differential index of $\mathcal{F}$ and they are denoted by $\text{ddim} \mathcal{F}$ and $\text{dind} \mathcal{F}$, respectively. The algebra $\mathcal{F}$ is called complete if:

$$\text{ddim} \mathcal{F} + \text{dind} \mathcal{F} = \dim M + \text{corank} \{\cdot, \cdot\},$$

If $\mathcal{F}$ is any algebra of functions, then we shall say that $\mathcal{A} \subset \mathcal{F}$ is a complete subalgebra if

$$\text{ddim} \mathcal{A} + \text{dind} \mathcal{A} = \text{ddim} \mathcal{F} + \text{dind} \mathcal{F}.$$  

The Hamiltonian system $\dot{x} = X_H(x)$ is completely integrable in the non-commutative sense if it possesses a complete algebra of first integrals $\mathcal{F}$. Then (under compactness condition) $M$ is almost everywhere foliated by $(\text{dind} \mathcal{F} - \text{corank} \{\cdot, \cdot\})$-dimensional invariant isotropic tori. Similarly as in the Liouville theorem, the tori are filled up with quasi-periodic trajectories.

Mishchenko and Fomenko stated the conjecture that non-commutative integrable systems $\dot{x} = X_H(x)$ are integrable in the usual commutative sense by means of integrals from $\mathcal{A}$ that belong to the same functional class as the original non-commutative algebra of integrals. The conjecture is proved in $C^\infty$–smooth case [?]. In the analytic case, when $\mathcal{F} = \text{span}_\mathbb{R}\{f_1, \ldots, f_l\}$ is a finite-dimensional Lie algebra, the conjecture has been proved by Mishchenko and Fomenko in the semisimple case and just recently by Sadetov [?] for arbitrary Lie algebras.

Now, let a connected compact Lie group $G$ act on a $2n$-dimensional connected symplectic manifold $(M, \omega)$. Suppose the action is Hamiltonian with the momentum mapping $\Phi : M \to \mathfrak{g}^*$ ($\mathfrak{g}^*$ is the dual space of the Lie algebra $\mathfrak{g}$, we use the identification by means of $\text{Ad}_G$-invariant scalar product $\langle \cdot, \cdot \rangle$ on $\mathfrak{g}$).

Consider the following two natural classes of functions on $M$. Let $\mathcal{F}_1$ be the set of functions in $C^\infty(M)$ obtained by pulling-back the algebra $C^\infty(\mathfrak{g})$ by the moment map $\mathcal{F}_1 = \Phi^* C^\infty(\mathfrak{g})$. Let $\mathcal{F}_2$ be the set of $G$–invariant functions in $C^\infty(M)$. The mapping $f \mapsto f \circ \Phi$ is a morphism of Poisson structures:

$$\{f \circ \Phi, g \circ \Phi\}(x) = \{f, g\}_{\mathfrak{g}}(\eta), \quad \eta = \Phi(x),$$

where $\{\cdot, \cdot\}_{\mathfrak{g}}$ is the Lie-Poisson bracket on $\mathfrak{g}$:

$$\{f, g\}_{\mathfrak{g}}(\eta) = \langle \eta, [\nabla f(\eta), \nabla g(\eta)] \rangle, \quad f, g : \mathfrak{g} \to \mathbb{R}.$$
Thus, \( F_1 \) is closed under the Poisson bracket. Since \( G \) acts in a Hamiltonian way, \( F_2 \) is closed under the Poisson bracket as well. The second essential fact is that \( h \circ \Phi \) commute with any \( G \)-invariant function (the Noether theorem). In other words: \( \{ F_1, F_2 \} = 0 \).

The following theorem, although it is a reformulation of some well known facts about the momentum mapping (e.g., see [?]), is fundamental in the considerations below (see [?] for more details).

Let \( A \subset C^\infty(\mathfrak{g}) \) be a Lie subalgebra and \( \Phi^* A = \{ h \circ \Phi, h \in A \} \) the pull-back of \( A \) by the momentum mapping. Then we have:

**Theorem 1** (i) The algebra of functions \( F_1 + F_2 \) is complete:

\[
\text{ddim } (F_1 + F_2) + \text{dind } (F_1 + F_2) = \dim M.
\]

The dimension of regular invariant isotropic tori, common level sets of functions from \( F_1 + F_2 \), is equal to

\[
\dim G_\mu - \dim G_x.
\]

for generic \( x \in M, \mu = \Phi(x) \) (\( G_\mu \) and \( G_x \) denotes the isotropy groups of \( G \) action at \( \mu \) and \( x \)).

(ii) \( \Phi^* A + F_2 \) is a complete algebra on \( M \) if and only if \( A \) is a complete algebra on a generic adjoint orbit \( \mathcal{O}(\mu) \subset \Phi(M) \).

(iii) If \( B \) is complete (commutative) subalgebra of \( F_2 \) and \( A \) is complete (commutative) algebra on the orbit \( \mathcal{O}(\mu) \), for generic \( \mu \in \Phi(M) \) then \( \Phi^* A + B \) is complete (commutative) algebra on \( M \).

Notice that instead of commutative subalgebras one usually consider sets of commuting functions. Clearly, each commutative set generates a certain commutative subalgebra. The notions of completeness, \( \text{ddim} \) and \( \text{dind} \) for a commutative set are defined just in the same way as above.

### 3 Magnetic Geodesic Flows

Let \( G \) be a compact connected Lie group with the Lie algebra \( \mathfrak{g} = T_e G \). Let us fix some bi-invariant metric \( ds_0^2 \) on \( G \), i.e., \( \text{Ad}_G \)-invariant scalar product \( \langle \cdot, \cdot \rangle \) on \( \mathfrak{g} \). We can identify \( \mathfrak{g}^* \) and \( \mathfrak{g} \) by \( \langle \cdot, \cdot \rangle \).

Consider an arbitrary homogeneous space \( G/H \) of the Lie group \( G \). The metric \( ds_0^2 \) induces so called normal metric on \( G/H \). We shall denote the normal metric also by \( ds_0^2 \). By the use of \( ds_0^2 \) we identify \( T^*G \cong TG \) and \( T^*(G/H) \cong T(G/H) \). Let \( \mathfrak{h} \) be the Lie algebra of \( H \) and \( \mathfrak{g} = \mathfrak{h} + \mathfrak{v} \) the orthogonal decomposition. Then \( \mathfrak{v} \) can be naturally identified with \( T_{\pi(e)}(G/H) \) and \( T_{\pi(e)}^*(G/H) \), where \( \pi : G \rightarrow G/H \) is the canonical projection.

**Construction of the Magnetic Field.** We introduce a class of homogeneous spaces \( G/H \) having a natural construction of the magnetic term, consisting of pairs \((G,H)\), where \( H \) have one-point adjoint orbits. Let \( a \in \mathfrak{h} \) be the \( H \)-adjoint invariant. Then \( H \) is a subgroup of the \( G \)-adjoint isotropy group \( G_a \) of
\(a\). The adjoint action \(\mathcal{O}(a)\) through \(a\) carries the Kirillov-Konstant symplectic form \(\Omega_{KK}\). Then we have canonical submersion of homogeneous spaces

\[
\sigma : G/H \rightarrow G/G_a \cong \mathcal{O}(a)
\]

and the closed two-form \(\Omega = \sigma^* \Omega_{KK}\) gives us the required magnetic field on \(G/H\).

The form \(\Omega\) is \(G\)-invariant. From the definition of \(\Omega_{KK}\) (see equation (??)) one can easily prove that at the point \(\pi(e)\), \(\Omega\) is given by

\[
\Omega(\xi_1, \xi_2)_{\pi(e)} = -\langle a, [\xi_1, \xi_2] \rangle, \quad \xi_1, \xi_2 \in \mathfrak{v} \cong T_{\pi(e)}(G/H)
\]  

(5)

Below we give another natural description of the form \(\Omega\).

**Reduction.** Consider the right action of the Lie subgroup \(H\) to \(G\): \((g, h) \mapsto gh, g \in G, h \in H\), and extend it to the right Hamiltonian action on \(T^*G\). After identification \(\mathfrak{h} \cong \mathfrak{h}^*\), we get the momentum mapping

\[
\Psi : T^*G \rightarrow \mathfrak{h}, \quad \Psi(g \cdot \xi) = \text{pr}_\mathfrak{h} \xi, \quad \xi \in \mathfrak{g}.
\]

Here \(\text{pr}_\mathfrak{h}\) denotes the orthogonal projection with respect to the invariant scalar product \(\langle \cdot, \cdot \rangle\).

It is well known that the symplectic reduced space \(\Psi^{-1}(0)/H\) is symplectomorphic to \((T^*(G/H), \omega)\), where \(\omega\) is the canonical symplectic form on \(T^*(G/H)\). On the other side, the reduced spaces \(\Psi^{-1}(a)/H_a\), are diffeomorphic to the fibre bundles over \(T^*(G/H)\) with fibres being the \(H\)-adjoint orbit through \(a\). In particular, if we deal with one-point orbit \(\mathcal{O}_H(a) = \{a\}\), then the reduced space is symplectomorphic to the magnetic cotangent bundle of \(G/H\) (see [?],[?]). Note that for connected \(H\), \(a\) is a \(H\)-adjoint invariant if and only if \(a\) belongs to the center of \(\mathfrak{h}\).

**Proposition 1** Let \(a \in \mathfrak{h}\) be the \(H\)-adjoint invariant and let \(e\) be a real parameter. Then the symplectic reduced space \(\Psi^{-1}(\epsilon a)/H\) is symplectomorphic to the magnetic cotangent bundle \(T^*(G/H)\) endowed with the symplectic form \(\omega + \epsilon \rho \Omega\). The form \(\Omega\) is \(G\)-invariant and at the point \(\pi(e)\) is given by (??).

**Proof.** We only need to describe the magnetic term for \(\epsilon = 1\). Take a principal connection \(\alpha\) on the \(H\)-bundle \(G \rightarrow G/H\), that is a \(\mathfrak{h}\)-valued 1-form with the property that the distribution \(D = \ker \alpha \subset TG\) (horizontal distribution) is \(H\)-invariant and transversal to the orbit of \(H\)-action. For example we can take \(\alpha\) such that \(D\) is orthogonal to \(H\)-orbits with respect to the fixed bi-invariant metric. Then \(\alpha_g(X) = \text{pr}_\mathfrak{h}(g^{-1}X)\) and \(D_g = g \cdot \mathfrak{v}\). Define the 1-form \(\alpha_g = \langle a, \alpha \rangle\) on \(G\). The magnetic form \(\Omega\) is the unique 2-form determined by (see Kummer [?])

\[
d\alpha \equiv \pi^* \Omega.
\]

Since \(\alpha\) is a connection and \(a\) is \(H\)-invariant, the form \(\Omega\) is well defined. Also, since \(\pi\) is a submersion, \(\Omega\) is closed but need not be exact.
For a vector $X \in T_gG$ we have the unique decomposition $X = X^h + X^v$, into the horizontal part $X^h \in g \cdot \mathfrak{h}$ and the vertical part $X^v \in g \cdot \mathfrak{h}$. The alternative description of the magnetic term is

$$\Omega_{\pi(g)}(X, Y) = \langle a, \beta_g(X^h, Y^h) \rangle, \quad X, Y \in T_{\pi(g)}(G/H)$$

where $X^h, Y^h \in T_gG$ are horizontal lifts of $X$ and $Y$ and $\beta$ is the curvature of the connection ($\mathfrak{h}$-valued 2-form on $G$).

Let $X^h, Y^h$ be arbitrary extensions of $X^h, Y^h$ to horizontal vector fields. Then

$$\beta(X^h, Y^h) = -\alpha([X^h, Y^h])$$

where $[\cdot, \cdot]$ is the commutator of vector fields. Now, by taking the left-invariant extensions of $X^h$ and $Y^h$ we come to the expression

$$\beta(X^h, Y^h) = -\text{pr}_h[g^{-1} \cdot X^h, g^{-1} \cdot Y^h],$$

where $[\cdot, \cdot]$ is the Lie algebra commutator.

The horizontal lifts of $\xi_1, \xi_2 \in \mathfrak{v} \cong T_{\pi(g)}(G/H)$ to $\mathfrak{g} \cong T_eG$ are exactly $\xi_1$ and $\xi_2$ considered as elements of $\mathfrak{g}$. Whence, from relations (??) and (??) we get the required expression (??) for the magnetic form $\Omega$ at $\pi(e)$. $\Box$

Note that the above magnetic cotangent bundles of the homogeneous spaces naturally appear in the symplectic induction procedure over a point (see ??).

The natural left $G$-action on $T^*G$ commutes with the right $H$-action and leaves the preimage $\Psi^{-1}(ea)$ invariant. Thus, from the well known formula for the momentum mapping of the left $G$-action on $T^*G$ we get

**Lemma 1** The momentum mapping

$$\Phi_e : T^*(G/H) \to \mathfrak{g},$$

of the natural $G$-action on $T^*(G/H)$ with respect to the symplectic form $\omega + \epsilon^* \Omega$ is given by

$$\Phi_e(g \cdot \eta) = \text{Ad}_g(\eta + \epsilon a), \quad \eta \in \mathfrak{v}, \: g \cdot \eta \in T^*_{\pi(g)}(G/H).$$

**Magnetic Geodesic Flows of Normal Metrics.** The Hamiltonian function of the geodesic flow of the normal metric $ds^2_0$ is simply given by

$$H_0 = \frac{1}{2} \langle \Phi_0, \Phi_0 \rangle.$$

Now, let $\mathcal{F}_1$ be the algebra of all analytic, polynomial in momenta, functions of the form

$$\mathcal{F}_1 = \{ p \circ \Phi_e, \: p \in \mathbb{R}[\mathfrak{g}] \}$$

and $\mathcal{F}_2$ be the algebra of all analytic, polynomial in momenta, $G$-invariant functions on $T^*(G/H)$. Then

$$[\mathcal{F}_1, \mathcal{F}_2]_c = 0,$$
where \{ \cdot, \cdot \}_\omega are magnetic Poisson bracket with respect to \omega + \epsilon \rho^* \Omega.

Consider the Hamiltonian \( H_\epsilon = \frac{1}{2}(\Phi_\epsilon, \Phi_\epsilon) \in \mathcal{F}_1^\epsilon \). We have

\[
H_\epsilon(g \cdot \eta) = \frac{1}{2} \langle \text{Ad}_g \eta, \text{Ad}_g \eta \rangle + \epsilon \langle \text{Ad}_g \eta, \text{Ad}_g a \rangle + \epsilon^2 \frac{1}{2} \langle \text{Ad}_g a, \text{Ad}_g a \rangle
\]

\[
= H_0(g \cdot \eta) + \epsilon \frac{1}{2} \langle a, a \rangle = H_0(g \cdot \eta) + \text{const},
\]

where we used that \( \eta \in \mathfrak{v} \) is orthogonal to \( a \in \mathfrak{h} \). Thus, we see that Hamiltonian flows of \( H_0 \) and \( H_\epsilon \) coincides: \( \tilde{f} = \{ f, H_0 \}_\epsilon = \{ f, H_\epsilon \}_\epsilon \). Since \( H_\epsilon \) belongs to \( \mathcal{F}_1^\epsilon \) its commutes with \( \mathcal{F}_2 \). On the other side, as a composition of the momentum mapping with an invariant polynomial, the function \( H_\epsilon \) is also \( G \)-invariant and commutes with \( \mathcal{F}_1^\epsilon \). Hence \( \{ H_\epsilon, \mathcal{F}_1^\epsilon + \mathcal{F}_2 \}_\epsilon = 0 \).

From the above consideration and Theorem ?? we get the following result. Let, as before, \( G \) be a compact Lie group and \( H \subset G \) be a closed subgroup such that \( \text{Ad}_H a = a \) for a certain element \( a \in \mathfrak{h} \subset \mathfrak{g} \).

**Theorem 2** The magnetic geodesic flow of the normal metrics \( ds^2_\omega \) on the homogeneous space \( G/H \) with respect to the closed 2-form \( \epsilon \Omega \) given by (?) is completely integrable in the non-commutative sense. The complete algebra of first integrals is \( \mathcal{F}_1^\epsilon + \mathcal{F}_2 \).

**Remark 1** The magnetic geodesic flow can be seen also as the reduction of the geodesic flow of the bi-invariant metric \( ds^2_\omega \) from the invariant subspace \( \Psi^{-1}(\epsilon a) \) to \( \Psi^{-1}(\epsilon a)/H \cong T^*(G/H) \). With the above notation, this means that each magnetic geodesic line on \( G/H \) is the projection of a certain geodesic \( \gamma(t) \subset G \)

\[
\gamma(t) = g_0 \cdot \exp((\xi + \epsilon a)t), \quad t \in \mathbb{R},
\]

where \( \xi \in \mathfrak{g} \) and \( g_0 \) is the initial position. In such a way, the integrability of the magnetic geodesic flow can be also studied from the point of view of the symplectic reduction (see [? , ?]). More precisely, the reduction of the normal geodesic system from \( T^*G \) to the Poisson manifold \( (T^*G)/H \) is completely integrable in non-commutative sense (see Zung [?]). Since the symplectic leaves in \( (T^*G)/H \) are Marsden-Weinstein reduced spaces, it appears that the symmetry reduction for a generic value of the momentum map \( \Psi \) yields a system which is integrable in the non-commutative sense. The interpretation of these reduced systems in terms of the Yang-Mills analogue of the Lorentz force is well-known (e.g., see [?]). The magnetic bundle \( \Psi^{-1}(\epsilon a)/H \), in general, corresponds to a singular leaf in \( (T^*G)/H \) and in this case some complementary work has to be given to prove the integrability.

**Magnetic Geodesic Flows on Adjoint Orbits.** Consider the (co)adjoint action of \( G \) and the \( G \)-orbit \( O(a) \) through an element \( a \in \mathfrak{g} \). In what follows, we shall use the representation of the adjoint orbit as a homogeneous space \( G/H \), where \( H = G_a \) is the isotropy group of \( a \). Since \( G \) is a compact connected Lie group, \( G_a \) is also connected (e.g., see [?], page 259). We have

\[
\text{ann}(a) = \{ \xi \in \mathfrak{g}, [\xi, a] = 0 \} = T_e G_a.
\]
By definition, the Kirillov-Konstant symplectic form $\Omega_{KK}$ on $G/G_a$ is a $G$–invariant form, given at the point $\pi(e) \in G/G_a$ by

$$\Omega_{KK}(\xi_1, \xi_2)|_{\pi(e)} = -\langle a, [\xi_1, \xi_2] \rangle, \quad \xi_1, \xi_2 \in \text{ann}(a)^\perp = [a, \mathfrak{g}], \quad (10)$$

where $\xi_1, \xi_2$ are considered as tangent vectors to the orbit at $\pi(e)$. It follows from Proposition ?? that the Kirillov-Konstant form can be seen as a magnetic form obtained after right symplectic $G_a$-reduction of $T^*G$ as well.

From Theorem ?? we recover the Efimov result [?] (see also [?]):

**Corollary 1** Let $G$ be a compact Lie group and $a \in \mathfrak{g}$. The magnetic geodesic flows of normal metric $ds_a^2$ on the (co)adjoint orbit $\mathcal{O}(a) = G/G_a$ with respect to the magnetic form $\epsilon \Omega_{KK}$ is completely integrable in the non-commutative sense.

**Remark 2** For a generic $\eta \in \text{ann}(a)^\perp$ we have equality $\dim G_{\eta+\epsilon a} = \dim G_\eta$ for all $\epsilon \in \mathbb{R}$ (see [?]). It implies that the dimension of the regular invariant tori does not depend on $\epsilon$ and is equal to

$$\dim (\mathcal{F}_1^\eta + \mathcal{F}_2) = \dim G_\eta - \dim(G_a)_\eta, \quad (11)$$

for a generic element $\eta \in \text{ann}(a)^\perp$ (see [?]). Therefore, the influence of the magnetic fields $\epsilon \Omega_{KK}$, $\epsilon \in \mathbb{R}$ reflects as a deformation of the foliation of the phase space $(T^*\mathcal{O}(a), \omega + \epsilon \rho^*\Omega_{KK})$ by invariant isotropic tori. As the magnetic field increases, the magnetic geodesic lines become more curved.

**Example 1** On the unit round sphere (see the next section), the magnetic geodesic lines are circles on the sphere. It can be easily proved that for the motion with unit velocity, the radius of the circles is equal to $r_\epsilon = \arctg(\frac{1}{\sqrt{\epsilon}})$. As $|\epsilon|$ tends to infinity, $r_\epsilon$ tends to zero, and as $\epsilon$ tends to zero, then $r_\epsilon$ tends to $\frac{\pi}{2}$.

**Commutative Integrability.** To prove the commutative integrability, we use the argument shift method developed by Mischenko and Fomenko [?] as a generalization of Manakov’s construction [?].

Let $\mathbb{R}[\mathfrak{g}]^G$ be the algebra of $\text{Ad}_G$-invariant polynomials on $\mathfrak{g}$. Then the polynomials

$$\mathcal{A}_c = \{ p(\cdot + \lambda c), \lambda \in \mathbb{R}, p \in \mathbb{R}[\mathfrak{g}]^G \} \quad (12)$$

obtained from the invariants by shifting the argument are in involution with respect to the Lie-Poisson bracket [?]. Furthermore, for every adjoint orbit in $\mathfrak{g}$, one can find $c \in \mathfrak{g}$, such that $\mathcal{A}_c$ is a complete commutative set of functions on this orbit. For regular orbits it is shown in [?]. For singular orbits there are several different proofs, see [?, ?, ?]. Thus, the argument shift method allows us to construct a complete commutative subalgebra in $\mathcal{F}_1^\eta$.

The $G$-invariant, polynomial in momenta functions on $T^*(G/H)$ are in one-to-one correspondence with $\text{Ad}_H$-invariant polynomials on $\mathfrak{v}$, via their restrictions to $T^*_\mathfrak{v}(e)(G/H) \cong \mathfrak{v}$. Within this identification, from (??), (??) and
Thimm’s formula for $\epsilon = 0$ [?], the magnetic Poisson bracket $\{\cdot, \cdot\}_c$ on $T^*(G/H)$ corresponds to the following bracket on $\mathbb{R}[v]^H$

$$\{f, g\}_c^\bullet(\eta) = -\langle \eta + \epsilon a, [\nabla f(\eta), \nabla g(\eta)] \rangle, \quad f, g \in \mathbb{R}[v]^H,$$  \hspace{1cm} (13)

where $\mathbb{R}[v]^H$ denotes the algebra of $\text{Ad}_H$-invariant polynomials on $v$.

It is interesting that

$$\Lambda_{\lambda_1, \lambda_2} = \lambda_1 \{\cdot, \cdot\}_c^0 + \lambda_2 \{\cdot, \cdot\}_c^\bullet, \quad \lambda_1^2 + \lambda_2^2 \neq 0$$  \hspace{1cm} (14)

is a pencil of the compatible Poisson brackets on $\mathbb{R}[v]^H$. Here

$$\{f, g\}_c^\bullet(\eta) = -\langle a, [\nabla f(\eta), \nabla g(\eta)] \rangle, \quad f, g \in \mathbb{R}[v]^H.$$  \hspace{1cm} (15)

By the use of the pencil (??) and the completeness criterion derived in [?], for the case of adjoint orbits, i.e., when $H = G_a$ and $v = \text{ann}(a)^\perp$ one can conclude that the collection of Casimir functions of all the brackets $\Lambda_{\lambda_1, \lambda_2}$, $\lambda \in \mathbb{R}$:

$$B_a = \{p^\lambda_a(\eta) = p(\eta + \lambda a), \quad \lambda \in \mathbb{R}, \quad p \in \mathbb{R}[v]^G, \quad \eta \in \text{ann}(a)^\perp\}$$  \hspace{1cm} (16)

is a complete commutative subset in $\mathbb{R}[\text{ann}(a)^\perp]^G$ with respect to the canonical bracket $\Lambda_{1,0}$. If $a$ is regular in $g$ then $G_a$ is a maximal torus. In this case the completeness of $B_a$ can be easily verified (e.g., see [?, ??]). A nontrivial generalization to singular orbits of classical groups is done in [?, ??] and by Mykytyuk and Panasyuk for a general case [?]. Namely, it is proved that all (complexified) brackets $\Lambda_{\lambda_1, \lambda_2}$ have the same corank in a generic point $\eta \in \text{ann}(a)^\perp$ equal to (??). It follows from Theorem 1.1 [?] that (??) is a complete commutative algebra with respect to each Poisson bracket (??) as well.

Whence, according Theorem ??, we get the following statement

**Theorem 3** The magnetic geodesic flows of the normal metric $ds^2_0$ on the orbit $O(a) = G/G_a$, with respect to the magnetic field $c\Omega_K$ is completely integrable in the commutative sense, by means of analytic, polynomial in momenta first integrals $\Phi_c(\mathcal{A}_c) + B_a$, where $\mathcal{A}_c$ and $B_a$ are given by (??) and (??), respectively.

The commutative integrability of the magnetic flows on the complex projective spaces is proved by Efimov in [?] (since the complex projective spaces are symmetric spaces, in this case the algebra of $\mathcal{F}_2$ is commutative).

The integrals $B_a$ can be used for deforming the normal metric to a certain class of $G$-invariant metrics on $O(a)$ with completely integrable magnetic geodesic flows. Theorem ?? is announced in [?], where one can find the explicit description of the deformed flows within the standard representation of the orbit $O(a)$, as a submanifold of $g$.

**Remark 3** If $H$ is a subgroup of the isotropy group $G_a$, then the rank of the bracket $\Lambda_{0,1}$, in general, is smaller then the rank of the other brackets from the pencil. Then Theorem 1.1 [?] implies that Casimir functions of the brackets $\Lambda_{1,\lambda}$, $\lambda \in \mathbb{R}$ do not form a complete set with respect to the magnetic bracket (??). In order to get complete commutative algebra in $(\mathbb{R}[v]^H, \Lambda_{1,\epsilon})$, one has to find enough additional commutative functions among Casimirs of $\Lambda_{0,1}$.
4 Magnetic Pendulum on Adjoint Orbits

From now on, we shall consider the orbit $O(a)$ realised as a submanifold of $g$. In this representation, the geometry of Hamiltonian flows on $T^*O(a)$ is studied by Bloch, Brockett and Crouch [8], while $G$-invariant magnetic geodesic flows are studied in [9].

The tangent space at $x = \text{Ad}_g(a)$ is simply the orthogonal complement to $\text{ann}(x)$. Consider the cotangent bundle $T^*O(a)$ as a submanifold of $g \times g$:

$$T^*O(a) = \{(x, p) | x = \text{Ad}_g(a), p \in \text{ann}(x)^\perp\},$$

with the paring between $p \in T^*_xO(a) \cong \text{ann}(x)^\perp$ and $\eta \in T_xO(a)$ given by $p(\eta) = \langle p, \eta \rangle$. Then the canonical symplectic form $\omega$ on $T^*O(a)$ can be seen as a restriction of the canonical linear symplectic form of the ambient space $g \times g$:

$$\sum_{i=1}^{\dim g} dp_i \wedge dx_i, \quad \text{where } p_i, x_i \text{ are coordinates of } p \text{ and } x \text{ with respect to some base of } g.$$

Let $\xi \in g$ and $x = \text{Ad}_g(a)$. Since $\xi_x = \frac{d}{ds}\text{Ad}_{\exp(s\xi)}(x)|_{s=0} = [\xi, x]$, the momentum mapping of the Hamiltonian $G$-action

$$g \cdot (x, p) = (\text{Ad}_g x, \text{Ad}_g p)$$

on $(T^*O(a), \omega)$ is given by the relation $\langle \Phi_0(x, p), \xi \rangle = \langle p, \xi_x \rangle = \langle p, [\xi, x] \rangle$. That is

$$\Phi_0(x, p) = [x, p].$$

Therefore, the momentum mapping (14), for $\epsilon \neq 0$, and normal metric Hamiltonian read

$$\Phi_\epsilon(x, p) = [x, p] + \epsilon x,$$

$$H_0(x, p) = \frac{1}{2}\langle [x, p], [x, p] \rangle.$$

**Magnetic Spherical Pendulum.** As an example, consider the Lie group $SO(3)$. The Lie algebra $so(3)$ is isomorphic to the Euclidean space $\mathbb{R}^3$ with bracket operation being the standard vector product. The adjoint orbits are spheres $\langle \vec{x}, \vec{x} \rangle = \text{const.}$. Let us consider the unit sphere $S^2$ and its cotangent bundle $T^*S^2$ realized as a submanifold of $\mathbb{R}^6$:

$$T^*S^2 = \{ (\vec{x}, \vec{p}) \in \mathbb{R}^6 | \phi_1 = \langle \vec{x}, \vec{x} \rangle = 1, \phi_2 = \langle \vec{x}, \vec{p} \rangle = 0 \}. \tag{17}$$

The momentum mapping of the natural $SO(3)$ action on $(T^*S^2, \omega)$ is $\Phi_0 = \vec{x} \times \vec{p}$ and the Hamiltonian of the normal metric $dS^2_0$ reduces to $H = \frac{1}{2}\langle \vec{p}, \vec{p} \rangle$. This is the kinetic energy of the unit mass particle motion on the sphere. Adding the magnetic term $\epsilon \rho^* \Omega_{KK}$ to the canonical form represents the influence of the magnetic monopole with the force equal to $\epsilon \vec{x} \times \vec{p}$. It is well known that two famous integrable potential systems on the sphere remain integrable after
including the magnetic monopole, namely the spherical pendulum and the Neumann system. Let us consider the spherical pendulum. Then the Hamiltonian of the system becomes:

\[ H = \frac{1}{2} \langle \vec{p}, \vec{p} \rangle - \kappa \langle \vec{b}, \vec{x} \rangle, \tag{18} \]

where \( \vec{b} \) is a constant unit vector. The equations of the motion of the particle with the energy (18) under the influence of the magnetic force \( \epsilon \vec{x} \times \vec{p} \), in the redundant variables \((x, p)\) are

\[ \frac{d}{dt} \vec{x} = p, \quad \frac{d}{dt} \vec{p} = \kappa \vec{b} + \epsilon \vec{x} \times \vec{p} + \lambda \vec{x}, \]

where the reaction force \( \lambda \vec{x} \) is determined from the condition that the trajectory \((\vec{x}(t), \vec{p}(t))\) satisfies the constraints \( \phi_1 = 1, \phi_2 = 0 \). The system is completely integrable due to the linear first integral \( f = \langle \vec{b}, \vec{x} \times \vec{p} + \epsilon \vec{x} \rangle \).

**Generalization to Adjoint Orbits.** The natural generalization of the magnetic spherical pendulum to the orbit \( \mathcal{O}(a) \) is the natural mechanical system with the kinetic energy given by the normal metric \( ds_a^2 \) and the potential function \( V(x) = \langle b, x \rangle \), i.e., with Hamiltonian

\[ H(x, p) = \frac{1}{2} \langle [x, p], [x, p] \rangle - \langle b, x \rangle, \]

under the influence of the magnetic force field given by \( \epsilon \Omega_K \), where \( \Omega_K \) is the standard Kirillov-Kostant form. Similar systems on the complex projective spaces are studied in [7].

**Proposition 2** The equations of the magnetic pendulum, in redundant variables \((x, p)\), are given by

\[ \dot{x} = [x, [p, x]], \tag{19} \]

\[ \dot{p} = [p, [p, x]] + \epsilon [x, p] + b - prann(x) b. \tag{20} \]

**Proof.** The equations of the geodesic flow of the normal metric are derived in [7] (see also [7]). The flow is given by the equations:

\[ \dot{x} = [x, [p, x]], \tag{21} \]

\[ \dot{p} = [p, [p, x]]. \tag{22} \]

The magnetic and potential forces have no influence to the equation (21), while the second equation takes the form

\[ \dot{p} = [p, [p, x]] + b + \Pi + \Lambda, \tag{23} \]

where the Lagrange multiplier \( \Lambda \in \text{ann}(x) \) is determined from the condition that the trajectory \((x(t), p(t))\) belongs to \( T^\ast \mathcal{O}(a) \). On the other side, the magnetic
force $\Pi$ is equal to $\epsilon[x, p]$. For example, one can get this relation considering the magnetic geodesic flow of the normal metric (i.e., $V(x) \equiv 0$) and the conservation of the shifted momentum map

$$\Phi_x = [x, \hat{p}] + [\hat{x}, p] + \epsilon \hat{x} = [x, [p, x]] + \Pi + \Lambda + [\Pi, [p, x]] + \epsilon[x, [p, x]] = [x, \Pi + \epsilon[p, x]] = 0.$$  

In order to find $\Lambda$, take the (local) base $e_1(\bar{x}), \ldots, e_r(\bar{x})$, of $\text{ann}(\bar{x}) ([e_i(\bar{x}), \bar{x}]) = 0)$, which is orthonormal at $\bar{x} = x$. Then $\Lambda = \sum_{i=1}^{r} \lambda_i e_i(x)$. The Lagrange multipliers $\lambda_i$ are determined from the conditions

$$\frac{d}{dt}\langle p, e_i(x) \rangle = \langle \dot{p}, e_i(x) \rangle + \langle p, \dot{e}_i(x) \rangle = 0, \quad i = 1, \ldots, r \quad (24)$$

From the identity $[e_i(\bar{x}), \bar{x}] = 0$ we have $[\dot{e}_i(x), x] + [e_i(x), \bar{x}] = [\dot{e}_i(x), x] + [e_i(x), [p, x]]$. On the other side, the Jacobi identity gives $[e_i(x), x, [p, x]] = [\Pi, [p, x], e_i(x)]$. Therefore

$$\dot{\dot{e}}_i(x) + [p, x], e_i(x) \rangle \in \text{ann}(\bar{x}), \quad i = 1, \ldots, r. \quad (25)$$

Finally, combining (??), (??) and (??), we get $\lambda_i = -\langle b, e_i(x) \rangle$, i.e,

$$\Lambda = -pr_{\text{Ann}(\bar{x})} b.$$  

This proves (??). □

5 Integrability of Magnetic Pendulum

By the use of the momentum mapping $\Phi_x$, the equations of motion of the magnetic pendulum on the orbit $O(a)$, can be rewritten in the symmetric form

$$\dot{x} = [\Phi_x, x], \quad (26)$$

$$\Phi_x = [x, b]. \quad (27)$$

This system can be naturally understood via another representation of $(T^*O(a), \omega + \epsilon\rho^*\Omega_KK)$, as a coadjoint orbit in the dual space of semidirect product $\mathfrak{g} \oplus_{\text{ad}} \mathfrak{g}$.

Realization of $T^*O(a)$ in $(\mathfrak{g} \oplus_{\text{ad}} \mathfrak{g})^*$. To prove the complete integrability below, we shall introduce the semi direct product $\mathfrak{g} \oplus_{\text{ad}} \mathfrak{g}$ in a slightly unusual way, by the use of contraction of Lie algebras.

From now on we suppose that $G$ is a compact semisimple Lie group. Then for $\langle \cdot, \cdot \rangle$ we can take the Killing form multiplied by $-1$. Let $\mathfrak{g}^C = \mathfrak{g} \otimes \mathbb{C}$. Then $\mathfrak{g}^C$ is a semisimple complex Lie algebra. Denote by $\mathfrak{g}_0$ the real semisimple Lie algebra obtained from $\mathfrak{g}^C$:

$$\mathfrak{g}_0 = \mathfrak{g} \oplus i\mathfrak{g}, \quad i^2 = -1.$$  

13
Then \( \dim \mathfrak{g}_0 = \dim \mathfrak{g}^C = 2 \dim \mathfrak{g}^C = 2 \dim \mathfrak{g} \) and
\[
\text{rank}_C \mathfrak{g}^C = \text{rank} \mathfrak{g} = r, \quad \text{rank} \mathfrak{g}_0 = 2 \text{rank} \mathfrak{g} = 2r.
\]

Let \( p_1, \ldots, p_k \) be the set of basic homogeneous invariant polynomials on \( \mathfrak{g} \) considered as complex invariant polynomials on \( \mathfrak{g}^C \). Then their real and imaginary parts form a set of basic polynomial invariants on \( \mathfrak{g}_0 \).

The real algebra \( \mathfrak{g}_0 \) has the symmetric pair decomposition: \( \mathfrak{g}_0 = \mathfrak{g} + i \mathfrak{g} \):
\[
[\mathfrak{g}, \mathfrak{g}] \subset \mathfrak{g}, \quad [\mathfrak{g}, i \mathfrak{g}] \subset i \mathfrak{g}, \quad [i \mathfrak{g}, i \mathfrak{g}] \subset i \mathfrak{g},
\]
and one can consider the contraction of \( \mathfrak{g}_0 \): the real Lie algebra \( \mathfrak{g}_\theta \) with the same linear space as \( \mathfrak{g}_0 \) and the Lie bracket defined by
\[
[\xi_1 + i \eta_1, \xi_2 + i \eta_2] = [\xi_1, \xi_2] + [\eta_1, \xi_2] + [\xi_1, \eta_2], \quad \xi_i, \eta_i \in \mathfrak{g}.
\]

It is clear that \( \mathfrak{g}_\theta \) is the semidirect product \( \mathfrak{g} \oplus_{\text{ad}} i \mathfrak{g} \), where the second term \( i \mathfrak{g} \) is considered as a commutative subalgebra.

Now, identify \( \mathfrak{g}_5^* \) with \( \mathfrak{g}_\theta \) and \( \mathfrak{g}_5^* \) with \( \mathfrak{g}_0 \) by means of nondegenerate scalar product
\[
(\xi_1 + i \eta_1, \xi_2 + i \eta_2) = (\xi_1, \xi_2) - (\eta_1, \eta_2), \tag{28}
\]
which is proportional to the Killing form of \( \mathfrak{g}_0 \). Then the differential of a smooth function \( f \) on \( \mathfrak{g}_0 \) (or \( \mathfrak{g}_\theta \)) is \( \nabla f|_{\xi + i \eta} = \nabla \xi f - i \nabla \eta f \) and the Lie-Poisson brackets on \( \mathfrak{g}_0 \) and \( \mathfrak{g}_\theta \) become
\[
\{f, g\}_0(\xi + i \eta) = (\xi + i \eta, [\nabla \xi f - i \nabla \eta f, \nabla \xi g - i \nabla \eta g]) = (\xi, [\nabla \xi f, \nabla \xi g]) - (\xi, [\nabla \eta f, \nabla \eta g]) + (\eta, [\nabla \xi f, \nabla \eta g]) + [\nabla \xi f, \nabla \xi g]
\]
\[
\{f, g\}_\theta(\xi + i \eta) = (\xi + i \eta, [\nabla \xi f - i \nabla \eta f, \nabla \xi g - i \nabla \eta g]) = (\xi, [\nabla \xi f, \nabla \xi g]) + (\eta, [\nabla \xi f, \nabla \eta g]) + [\nabla \xi f, \nabla \xi g]
\]

Note that a generic symplectic leaf (coadjoint orbit) in \( (\mathfrak{g}_\theta, \{\cdot, \cdot\}_\theta) \) has the same dimension as the orbit in \( \mathfrak{g}_0 \), that is \( 2 \dim \mathfrak{g} - 2r \) (see [?]).

It is well known that the cotangent bundle to the orbit of the linear representation of a Lie group to the vector space can be seen as a coadjoint orbit in the dual space of the semidirect of the group with the vector space (e.g., see [?]). The similar statement holds for the magnetic cotangent bundles:

**Proposition 3** The mapping \( \Theta_x : T^* \mathcal{O}(a) \to (\mathfrak{g} \oplus_{\text{ad}} i \mathfrak{g})^* \) given by
\[
\Theta_x(x, p) = \Phi_x(x, p) + ix \tag{29}
\]
is a symplectomorphism between \( T^* \mathcal{O}(a) \) endowed with the twisted symplectic form \( \omega + \epsilon \rho^* \Omega_{KK} \) and the coadjoint orbit of the element \( ca + ia \) in \( (\mathfrak{g} \oplus_{\text{ad}} i \mathfrak{g})^* \) endowed with the canonical Kirillov-Konstant symplectic form.

Novikov and Schmeltzer have constructed such mapping for the orbits of coadjoint representation of the three-dimensional Euclidean space motion group
which are symplectomorphic to the magnetic cotangent bundles of the sphere (see [?]). This problem is further developed in [? , ?, ?, ?].

Proof. We use the following general statement. Suppose that we have a symplectic manifold $M$ endowed with a transitive Hamiltonian action of a certain Lie group $K$. Consider the corresponding momentum mapping $\Theta : M \rightarrow \mathfrak{t}^*$. Then from the standard properties of a momentum mapping it follows that

1) the image of $\Theta$ is a single coadjoint orbit $O \subset \mathfrak{t}^*$, 
2) $\Theta : M \rightarrow O$ is a symplectic covering.

In our case we just need to describe the transitive Hamiltonian action of the semidirect product $G \rtimes_{\text{Ad}} \mathfrak{g}$ on the cotangent bundle $T^*\mathcal{O}(a)$. Such an action exists and is very natural. Indeed, let us consider first the standard action of $G$ on the cotangent bundle $T^*\mathcal{O}(a)$. As we saw above, the corresponding momentum mapping is exactly $\Phi_c$. Now we extend this action by adding the following action of the vector space $\mathfrak{g}$:

$$\eta \cdot (x, p) = (x, p + \text{pr}_{\text{ann}(x)^\perp}(\eta)), \quad \eta \in \mathfrak{g},$$

(30)

where $x \in \mathcal{O}$, $p \in T_x^*\mathcal{O}(a) = \text{ann}(x)^\perp$. Whence the action of the whole semidirect product $G \rtimes_{Ad} \mathfrak{g}$ on $T^*\mathcal{O}(a)$ is given by:

$$(g, i\eta) \cdot (x, p) = (\text{Ad}_g x, \text{Ad}_g p + \text{pr}_{\text{ann}(\text{Ad}_g x)^\perp}(\eta)), \quad (g, i\eta) \in G \rtimes_{Ad} \mathfrak{g}.$$

It is easy to verify that this formula defines an action and this action is Hamiltonian. We know this for the first component, and the action of the second one (32) is generated by translations along the Hamiltonian vector fields of the functions

$$H_\eta(x) = -\langle x, \eta \rangle.$$

(Notice that this flow is the same for all structures $\omega + \epsilon \rho^*\Omega_{KK}$, $\epsilon \in \mathbb{R}$).

Thus the Hamiltonian with respect to $\omega + \epsilon \rho^*\Omega_{KK}$ corresponding to an element $\xi + i\eta \in \mathfrak{g} \oplus_{\text{ad}} i\mathfrak{g}$ takes the form:

$$H_{\xi + i\eta}(x, p) = H_\xi(x, p) + H_\eta(x, p)$$

$$= \langle \Phi_c(x, p), \xi \rangle - \langle x, \eta \rangle = (\Phi_c(x, p) + ix, \xi + i\eta)$$

This implies that the formula for the momentum mapping is given by (32), where we use the natural identification of $(\mathfrak{g} \oplus_{\text{ad}} i\mathfrak{g})^*$ and $\mathfrak{g} \oplus_{\text{ad}} i\mathfrak{g}$ by means of the scalar product (32).

Since the above action is obviously transitive, we conclude that $\Theta_c$ is a symplectic covering over a certain coadjoint orbit. It is not hard to verify that $\Theta_c$ is one-to-one with the image, and therefore is a global symplectomorphism, as required. $\square$

Compatible Poisson Brackets and Integrability. Since the Hamiltonian flow

$$\dot{f} = \{f, h\}_{\mathfrak{g}^*}$$
of $h(\xi + i\eta) = \frac{1}{2} \langle \xi, \xi \rangle - \langle b, \eta \rangle$ is given by

$$\frac{d}{dt}(\xi + i\eta) = [\eta, b] + i[\xi, \eta],$$

(31)

from Proposition ?? we reobtain the equations (??), (??).

The flow (??) is completely integrable. This is related to the general construction of integrable systems by the use of symmetric pair decompositions of Lie algebras and compatibility of Poisson brackets $\{\cdot, \cdot\}_{\mathfrak{g}_0}$, $\{\cdot, \cdot\}_{\mathfrak{g}_b}$ and $\{\cdot, \cdot\}_{\mathfrak{i}b}$, where

$$\{f, g\}_{\mathfrak{g}_0}(\xi + i\eta) = (ib, [\nabla_{\xi} f - i\nabla_{\eta} f, \nabla_{\xi} g - i\nabla_{\eta} g])$$

$$= (b, [\nabla_{\xi} f, \nabla_{\eta} g] + [\nabla_{\eta} f, \nabla_{\xi} g])$$

(Reyman [?], see also [??]).

Let $\mathfrak{A}$ be the algebra of linear functions on $\text{ann}(b)$, lifted to the linear functions on $\mathfrak{g}_0$:

$$\mathfrak{A} = \{f_\mu(\xi + i\eta) = \langle \mu, \xi \rangle, \mu \in \text{ann}(b)\}$$

and let

$$\mathfrak{B} = \{\text{Re}(p_j(\lambda\xi + i(\eta + \lambda^2 b)), \text{Im}(p_j(\lambda\xi + i(\eta + \lambda^2 b)), \lambda \in \mathbb{R}, j = 1, \ldots, r\}, \quad (32)$$

where $p_j$ are basic invariant polynomials of the Lie algebra $\mathfrak{g}^C$. Then $\mathfrak{B}$ is commutative, and $\mathfrak{A} + \mathfrak{B}$ is a complete (non-commutative) set of integrals of (??) (see [?] or Theorem 1.5 in [?]).

From Proposition ?? we get

**Corollary 2** The magnetic pendulum system (??), (??) is completely integrable on a generic orbit $\mathcal{O}(\mathfrak{g})$. The complete set of integrals is

$$\Theta^*_t(\mathfrak{A} + \mathfrak{B}) = \{f(\Phi_t(x, p) + ix), f \in \mathfrak{A} + \mathfrak{B}\}.$$
Proof. $\Theta^*\mathcal{B}$ is complete on $\left(T^*\mathcal{O}(a),\omega + \epsilon \rho^*\Omega_{KK}\right)$ if and only if $\mathcal{B}$ is complete on the coadjoint orbit $\Theta_\epsilon(T^*\mathcal{O}(a))$.

Consider the pencil of compatible Poisson structures

$$\Lambda_{\lambda_1,\lambda_2} = \lambda_1 \{\cdot,\cdot\}_g + \lambda_2 \{\cdot,\cdot\}_g + \{\cdot,\cdot\}_b, \quad \lambda_1, \lambda_2 \in \mathbb{R}, \lambda_1^2 + \lambda_2^2 \neq 0.$$

The functions (2.1) are Casimir functions for $\Lambda_{\lambda_1,\lambda_2}$, where $\lambda_1 + \lambda_2 \neq 0$, $\lambda_2 \neq 0$, $\lambda = \sqrt{\lambda_2/(\lambda_2 + \lambda_1)}$ [2]. Since we deal with analytic functions, we only need to prove the completeness of $\mathcal{B}$ at one point in $\Theta_\epsilon(T^*\mathcal{O}(a))$. Also, the completeness of $\mathcal{B}$ for one element $b$ implies the completeness for a generic $b \in \mathfrak{g}$.

Consider the point $ea + ia \in \Theta_\epsilon(T^*\mathcal{O}(a))$ and take an arbitrary regular element $b \in \text{ann}(a)$. According Theorem 1.1 [2], $\mathcal{B}$ is complete at $ea + ia$ with respect to the Poisson bracket $\Lambda_{1,0} = \{\cdot,\cdot\}_g$ if and only if

1. $\text{rank} \Lambda_{\lambda_1,\lambda_2} = 2 \dim \mathfrak{g} - 2r$, for all $(\lambda_1, \lambda_2) \neq (1,0)$.
2. $\dim \{\xi + i\eta \in \ker \Lambda_{1,0} | \Lambda_{1,0}(\xi + i\eta, \ker \Lambda_{1,0}) = 0\} = 2r$.

Here the Poisson brackets $\Lambda_{\lambda_1,\lambda_2}$ are taken at the point $ea + ia$ and they are considered as skew-symmetric bilinear forms on $\mathfrak{g}_0$. Furthermore, all objects are assumed to be (again) complexified.

Since $b$ is a regular element in $\mathfrak{g}$, it follows that $ib$ is a regular element of the semisimple Lie algebra $\mathfrak{g}_0$:

$$\text{ann}_{\mathfrak{g}_0}(ib) = \text{ann}_{\mathfrak{g}}(b) + i\text{ann}_{\mathfrak{g}}(b).$$

($\text{ann}_2(b)$ is a maximal commutative subalgebra of $\mathfrak{g}$.)

The condition (A1), for $\lambda_1 + \lambda_2 \neq 0$ is equivalent to the regularity of the elements $\lambda ea + ia + \lambda^2 ib$, $\lambda \in \mathbb{C}$, $\lambda \neq 0$, in the Lie algebra $\mathfrak{g}_0$. This follows easily from the regularity of $ib$.

Now, consider the skew-symmetric form $\Lambda_{-1,1}$. We have

$$\Lambda_{-1,1}(\xi_1 - i\eta_1, \xi_2 - i\eta_2) = -(ea + ia, [\xi_1 - i\eta_1, \xi_2 - i\eta_2]_g) + (ea + ia, [\xi_1 - i\eta_1, \xi_2 - i\eta_2]) + (ib, [\xi_1 - i\eta_1, \xi_2 - i\eta_2]) = -(ea, [\eta_1, \eta_2]) + [b, [\xi_1, \eta_2] + [\eta_1, \xi_2]].$$

Therefore, $\xi - i\eta \in \ker \Lambda_{-1,1}$ if and only if

$$[b, \eta] = 0, \quad [\xi, b] = [\eta, ea] = 0.$$

The first equation yields $\eta \in \text{ann}_\mathfrak{g}(b)$. On the other hand, since $b \in \text{ann}_\mathfrak{g}(a)$, we have $[\text{ann}_\mathfrak{g}(b), a] = 0$. Thus, the second equation reduces to $[\xi, b] = 0$, i.e., $\xi \in \text{ann}_\mathfrak{g}(b)$ and

$$\dim \ker \Lambda_{-1,1} = 2r.$$

It remains to verify (A2). We have

$$\Lambda_{1,0}(\xi_1 - i\eta_1, \xi_2 - i\eta_2) = (ea + ia, [\xi_1 - i\eta_1, \xi_2 - i\eta_2]_g) = (ea, [\xi_1, \xi_2]) + (a, [\xi_1, \eta_2] + [\eta_1, \xi_2]).$$

17
Similarly as above $\xi - i\eta$ belongs to $\ker \Lambda_{1,0}$ if and only if $[\xi, a] = 0$, $[\eta, a] = 0$, i.e.,

$$\ker \Lambda_{1,0} = \text{ann}_\mathfrak{g}(a) + i\text{ann}_\mathfrak{g}(a).$$

We need to find the dimension of the space

$$K = \{ \xi - i\eta \in \ker \Lambda_{1,0} | \Lambda_{0,1}(\xi - i\eta, \ker \Lambda_{1,0}) = 0 \} = \{ \xi - i\eta \in \ker \Lambda_{1,0} | (ea + ia + ib, [\xi - i\eta, \text{ann}_\mathfrak{g}(a) + i\text{ann}_\mathfrak{g}(a)]) = 0 \}
= \{ \xi - i\eta \in \ker \Lambda_{1,0} | (ib, [\xi - i\eta, \text{ann}_\mathfrak{g}(a) + i\text{ann}_\mathfrak{g}(a)]) = 0 \}.$$

Whence, $K$ consists of those elements in $\text{ann}_\mathfrak{g}(a) + i\text{ann}_\mathfrak{g}(a)$ which commute with $ib$. But, since $ib$ is a regular element of $\mathfrak{g}_0$, we find $\dim K = 2r$. The theorem is proved. $\square$

**Remark 4** From Corollary 2, by taking $b = 0$, we get complete integrability of the magnetic geodesic flows of normal metrics on regular orbits $O(a)$. It is interesting that in this case we have

$$\mathcal{F}^r_{1} = \Theta^*_r \mathfrak{A},$$

and $\Theta^*_r \mathfrak{B}$ coincides with the set of commuting $G$-invariant functions on $T^* O(a)$ obtained by shifting of argument (38):

$$\mathcal{B}_a = \Theta^*_r \mathfrak{B}.$$

In this sense, remarkably, the shifting of argument method [?] can be seen as a particular case of the method of contraction of Lie algebras [?, ?]. By modifying the proof of Theorem 2, it would be possible to give a proof of the completeness of $\mathcal{B}_a + \mathcal{F}^r_{1}$ on singular orbits $O(a)$, different from those given in [?, ?].

**Remark 5** As it follows from Reyman and Semenov-Tian-Shanski [?] (or by straightforward computation) the equations (39), (33) are equivalent to the L-A pair

$$\dot{\lambda}(\lambda) = [L(\lambda), A(\lambda)]$$

with a spectral parameter $\lambda$, where $L(\lambda) = \lambda\Phi_1 + i(x + \lambda^2b)$, $A(\lambda) = \Phi_0 + i\lambda b$. The integrals $\Theta^*_r \mathfrak{B}$ are exactly the integrals arising from the L-A representation of the system.
