SYMPLECTIC INVARIANTS FOR PARABOLIC ORBITS AND CUSP SINGULARITIES OF INTEGRABLE SYSTEMS

ALEXEY BOLSINOV, LORENZO GUGLIELMI AND ELENA KUDRYAVTSEVA

1. INTRODUCTION

An integrable Hamiltonian system on a symplectic manifold \((M^n, \Omega)\) is defined by \(n\) pairwise commuting functions \(F_1, \ldots, F_n\) which are independent on \(M^n\) almost everywhere. We will consider the case \(n = 2\) and denote commuting functions by \(H\) and \(F\). Under the above assumptions, we can introduce the structure of a singular Lagrangian fibration on \(M^4\) whose fibers are, by definition, common level surfaces \(L_{h,f} = \{H = h, F = f\}\), \((h,f) \in \mathbb{R}^2\) or their connected components. We assume that all the fibers are compact (unless we study local properties of a system). The functions \(H\) and \(F\) also define a Hamiltonian \(\mathbb{R}^2\)-action on \(M^4\).

According to Liouville theorem, regular compact connected fibers are 2-dimensional Lagrangian tori which coincide with orbits of the \(\mathbb{R}^2\)-action. We say that a fiber \(L_{h,f}\) is singular if it contains a singular point, i.e., a point \(P\) such that \(dH(P)\) and \(dF(P)\) are linearly dependent. Equivalently, we may say that \(L_{h,f}\) is singular if it contains an orbit of a non-maximal dimension, i.e., 1 or 0. A general problem of the theory of singularities of integrable systems is to describe the topology of singular fibers and their saturated neighborhoods (similarly for singular orbits). Notice that the fact that \(F\) and \(H\) commute makes this theory rather different as compared to the classical singularity theory of smooth maps.

Description of singularities assumes at least three different settings: topological, smooth and symplectic. For instance, saying that two given singularities (points, orbits or fibers) are symplectically equivalent we mean the existence of a fiberwise symplectomorphism between their neighborhoods. Throughout the paper, in addition we assume that all the objects we are working with are real (or complex) analytic.

In this paper we discuss just one particular type of singularities, namely parabolic orbits and cuspidal tori (speaking informally, a cuspidal torus is a compact singular fiber that contains one parabolic orbit and no other singular points).

Recall that non-degenerate singular orbits in integrable Hamiltonian systems can be of two different types: elliptic and hyperbolic. In integrable systems of two degrees of freedom, we may often observe a transition from elliptic to hyperbolic in a smooth one-parameter family of singular orbits. At the very moment of transition, the orbit becomes degenerate and of parabolic type. This scenario is rather natural and motivates the name parabolic as transitional state between elliptic and hyperbolic. The terminology is borrowed from [25], such singularities are also known as cusp singularities [11], [13] and the latter is perhaps more common.

An important property of parabolic orbits is their stability under small integrable perturbations (see [15], [18]). This is one of the reasons why such orbits can be observed in many examples of integrable Hamiltonian systems: Kovalevskaya top [7], other integrable cases in rigid body dynamics including Steklov case, Clebsch case, Goryachev–Chaplygin–Sretenskii case, Zhukovskii case, Rubanovskii case and Manakov top on so(4) [3], as well as systems invariant w.r.t. rotations [19], [20], see also examples discussed in [13], [11]. Unlike non-degenerate singularities, however, in the literature on topology and singularities of integrable systems there are only few papers devoted to degenerate singularities including parabolic ones. We refer, first of all, to the following six — L. Lerman, Ya. Umanskii [25], V. Kalashnikov [18], N. T. Zung [28], H. Dullin, A. Ivanov [11], K. Efthathiou, A. Giacobbe [13] and Y. Colin de Verdière [8] — which we consider to be very important in the context of general classification programme for bifurcations occurring in integrable systems.
It is well known that from the smooth point of view, all parabolic orbits are equivalent, i.e., any two parabolic orbits admit fiberwise diffeomorphic neighborhoods (Lerman-Umanuskii [24, 25], Kalashnikov [18]). The same is true for cuspidal tori [13].

The simplest model for a parabolic singularity is as follows. Consider the direct product of $\mathbb{R}^3$ with coordinates $x, y, \lambda$ and a circle $S^1$ parametrised by $\varphi \mod 2\pi$ and two functions on this product $\mathbb{R}^3 \times S^1$:

\begin{equation}
H = x^2 + y^3 + \lambda y \quad \text{and} \quad F = \lambda.
\end{equation}

They commute with respect to the symplectic form

\begin{equation}
\Omega = dx \wedge dy + d\lambda \wedge d\varphi.
\end{equation}

The curve $\gamma_0(t) = (0, 0, 0, t)$ is a parabolic orbit of an integrable Hamiltonian system defined by commuting functions $H$ and $F$. However, in general, we cannot assume that these coordinates $x, y, \lambda, \varphi$ are canonical so that the formula for $\Omega$ can be different.

The starting point of the present paper was the following question. We know that elliptic and hyperbolic orbits have no symplectic invariants [26]. In other words, for any elliptic or hyperbolic (with orientable or non-orientable separatrix diagram) orbit there exists a symplectic canonical form, one and the same for all orbits of a given type (see, e.g., [2]). Is the same true for parabolic orbits or they admit non-trivial symplectic invariants?

It appears that non-trivial symplectic invariants do exist: a very simple invariant is given by Proposition 4.11. Moreover, we show that all symplectic invariants of parabolic orbits can be expressed in terms of action variables (Theorem 5.5). The next natural step would be to extend a fiberwise symplectomorphism between tubular neighborhoods of two parabolic orbits to saturated neighborhoods of the cuspidal tori that contain these orbits. This is done in Section 6: Theorem 6.1 (see also Remark 6.1) gives necessary and sufficient conditions for symplectic equivalence of cuspidal tori. This theorem basically says that the only symplectic semi-local invariant of a cuspidal torus is the canonical integer affine structure on the base of the corresponding singular Lagrangian fibration. In other words, cuspidal tori satisfy the following principle formulated in [5]:

Let $\phi: M \to B$ and $\phi': M' \to B'$ be two singular Lagrangian fibrations. If $B$ and $B'$ are affinely equivalent (as smooth stratified manifolds with singular integer affine structures), then these Lagrangian fibrations are fiberwise symplectomorphic.

Speaking less formally, this means that action variables allow us to completely reconstruct the symplectic structure. Such a property holds for many systems with non-degenerate singularities [9, 10, 12, 27] and even for integrable systems with incomplete flows [21]. Notice that this principle is also important in view of the global classification programme suggested by N.T.Zung in [29].

Although parabolic singularities are rather simple and specific, some of techniques developed and used in this paper are quite general and can be used for analysis of more complicated singularities. They also can be generalised to the case of many degrees of freedom.

Acknowledgements: This work was supported by the Russian Science Foundation (project no. 17-11-01303). We are very grateful to D. Guzzetti, A. Varchenko, S. Nemirovskii, N.T. Zung, A. Izosimov for valuable comments and discussions. We thank the referees for their comments and suggestions.

An extended version of this paper is available on arXiv.org, it contains some additional remarks and technical proofs which are not essential for understanding ideas and results presented below and, for this reason, have been removed from the journal version to make it more transparent and focused on key points. When appropriate, we give necessary references to [4].

2. PARABOLIC SINGULARITIES AND THEIR CANONICAL FORM (WITH NO SYMPLECTIC STRUCTURE INVOLVED)

Let $H$ and $F$ be a pair of Poisson commuting real-analytic functions on a real-analytic symplectic manifold $(M^4, \Omega)$. They define a Hamiltonian $\mathbb{R}^2$-action (perhaps local) on $M^4$. The dimension of the $\mathbb{R}^2$-orbit through a point $P \in M^4$ coincides with the rank of the differential of the momentum map $\mathcal{F} = (H, F): M^4 \to \mathbb{R}^2$ at this point. We are interested in one-dimensional orbits and without loss of generality we assume that $dF(P) \neq 0$. Consider the restriction of $H$ onto the three-dimensional level set of $F$ through $P$, that is, $H_0 := H|_{\{F=F(P)\}}$. We assume that the rank of $d\mathcal{F}$ at the point $P$ equals one. This is equivalent to any of the following:

- $P$ is a critical point of $H_0$;
- there exists a unique $k \in \mathbb{R}$ such that $dH(P) = k dF(P)$, in particular, $P$ is a critical point of $F - kH$. 

These properties hold true for each singular point \( P \) of rank one of the momentum map \( \mathcal{F} = (H, F) \) under the condition that \( d^2 F(P) \neq 0 \).

**Definition 2.1.** A point \( P \) (and the corresponding \( \mathbb{R}^2 \)-orbit through this point) is called **parabolic** if the following conditions hold:

(i) the quadratic differential \( d^2 H_0(P) \) has rank 1;

(ii) there exists a vector \( v \in \ker d^2 H_0(P) \) such that \( v^3 H_0 \neq 0 \) (by \( v^3 H_0 \) we mean the third derivative of \( H_0 \) along the tangent vector \( v \) at \( P \));

(iii) the quadratic differential \( d^2 (H - kF)(P) \) has rank 3, where \( k \) is the real number determined by the condition \( dH(P) = kdF(P) \).

**Remark 2.1.** In this definition, we use the third derivative of a function along a tangent vector which, in general, is not well defined. In our special case, however, this derivative makes sense as \( dH_0(P) = 0 \) and \( v \in \ker d^2 H_0(P) \). These two properties allow us to define it as follows:

\[
v^3(H_0) = \frac{d^3}{dt^3}|_{t=0} H_0(\gamma(t)),
\]

where \( \gamma(t) \) is an arbitrary curve on the hypersurface \( \{ F = F(P) \} \) such that \( \gamma(0) = P, \frac{d\gamma}{dt}(0) = v \). The result does not depend on the choice of \( \gamma(t) \).

**Remark 2.2.** It can be checked that in Definition 2.1, we may replace \( H \) and \( F \) by any other independent functions \( \tilde{H} = \tilde{H}(H, F), \tilde{F} = \tilde{F}(H, F) \) such that \( d\tilde{F}(P) \neq 0 \). In other words, the property of being **parabolic** refers to a singularity of the momentum map \( \mathcal{F} : M^4 \to \mathbb{R}^2 \) and does not depend on the choice of local coordinates in a neighborhood of \( \mathcal{F}(P) \in \mathbb{R}^2 \) (see [4] for details).

The following statement describes the structure of the singular Lagrangian fibration in a neighborhood of a parabolic point \( P \). As we are mostly interested in this fibration (rather than specific commuting functions \( H \) and \( F \) ), we allow ourselves to replace \( H \) with \( \tilde{H} = \tilde{H}(H, F) \) where \( \frac{\partial \tilde{H}}{\partial P} \neq 0 \) and to shift and change the sign of \( F \), so that \( \tilde{H} \) and \( \tilde{F} = \pm F + \text{const} \) still commute and define the same Lagrangian fibration as \( H \) and \( F \). Notice that according to Remark 2.2, \( P \) is parabolic for \( \tilde{H} \) and \( \tilde{F} \).

**Proposition 2.1.** In a neighborhood of a parabolic point \( P \) there exist a transformation

\[
\tilde{H} = \tilde{H}(H, F), \quad \text{with } \frac{\partial \tilde{H}}{\partial H} \neq 0,
\]

\[
\tilde{F} = \pm F + \text{const},
\]

and a local coordinate system \( x, y, \lambda, \varphi \) such that \( (x, y, \lambda, \varphi) |_{P} = (0, 0, 0, 0) \) and

\[
\tilde{H} = \tilde{H}(H, F) = x^2 + y^3 + \lambda y \quad \text{and} \quad \tilde{F} = \lambda.
\]

**Proof.** The proof of this statement if well known (e.g., [1, Sec. 1.5, Whitney’s Theorem] or [22, Statement 7.1]) but we still want to briefly explain some of its steps to reveal important underlying phenomena. The first step is to find \( x, y, \lambda, \varphi \) without touching \( H \) and \( F \).

**Lemma 2.2.** Under the above assumptions, there exist local coordinates \( x, y, \lambda, \varphi \) such that \( (x, y, \lambda, \varphi) |_{P} = (0, 0, F(P), 0) \) and

\[
H = \pm (x^2 + y^3 + b(\lambda)y + a(\lambda)), \quad F = \lambda,
\]

where \( a(\lambda) \) and \( b(\lambda) \) are real-analytic functions with \( b(F(P)) = 0, b'(F(P)) \neq 0 \).

**Proof.** Without loss of generality, we assume that \( H(P) = F(P) = 0 \). First of all we need to kill one dimension using the fact that \( H \) and \( F \) Poisson commute. Since \( dF(P) \neq 0 \) we can choose a canonical coordinate system \( p_1, q_1, p_2, q_2 \) such that \( F = q_2 \). Since \( H \) and \( F \) commute, we conclude that \( H \) does not depend on \( p_2 \), i.e., \( H = H(p_1, q_1, q_2) \). Thus, \( p_2 \) does not play any role, so we may forget about it and continue working with \( p_1, q_1, q_2 \).

Let us now think of \( H \) as a function of two variables \( q_1 \) and \( p_1 \) depending on \( q_2 = \lambda \) as a parameter. We have \( \partial H/\partial p_1 |_P = \partial H/\partial q_1 |_P = 0 \) and, without loss of generality, \( \partial^2 H/\partial p_1^2 |_P \neq 0 \). We are now in a quite standard situation in singularity theory.

By a parametric version of the Morse lemma, the function \( H \) can be written as \( H = \pm (x^2 + f(q_1, \lambda)) \), for some new local variable \( x = x(p_1, q_1, \lambda) \) such that \( x |_{P} = 0 \) and \( \partial x/\partial p_1 \neq 0 \). Now, condition (ii) of the definition of a parabolic point is satisfied if and only if the function \( f(q_1, 0) \) in one variable \( q_1 \) has order 3 at the point \( q_1 |_{P} \). Hence, this function can be written as \( \tilde{y}^3 \) for some variable \( \tilde{y} = \tilde{y}(q_1) \) with \( \tilde{y}(q_1(P)) = 0 \).
Now the function \( f(q_1, \lambda) \) is a 1-parameter “deformation” of the function \( f(q_1, 0) = \hat{y}^3 \) with the parameter \( \lambda \). It follows from [1, Sec. 8.2] that the deformation \( \hat{y}^3 + \lambda_2 \hat{y} + \lambda_1 \) is right-infinitesimally versal. By the versality theorem [1, Sec. 8.3], it is right-versal (for a definition of a versal deformation, see [1, Sec. 8.1]). Since any deformation is right-equivalent to a deformation induced from the right-versal one, we have \( f(q_1, \lambda) = \hat{y}^3 + b(\lambda) \hat{y} + a(\lambda) \) for some real-analytic functions \( y = y(\hat{y}, \lambda) \), \( a(\lambda) \) and \( b(\lambda) \) such that \( \hat{y}(\hat{y}, 0) = \hat{y}, a(0) = b(0) = 0 \). Since, by assumption, the quadratic differential \( d^2(H - kF)(P) \) has rank 3, we have \( b'(0) \neq 0 \). So, we obtain the representation (5).

Later on we will need to rearrange leaves of our singular Lagrangian fibration by using transformations of the form

\[
H \mapsto \tilde{H} = \tilde{H}(H, F), \quad F \mapsto \tilde{F} = \tilde{F}(H, F).
\]

We want to understand if such a transformation (acting on the base of the Lagrangian fibration) can be realised by a fiberwise analytic diffeomorphism upstairs. In other words, we want to know which of transformations (6) are liftable.

Let us look at the local bifurcation diagram (i.e. the set of critical values) of the momentum map defined by \( H \) and \( F \) from (5). This bifurcation diagram is as follows (for the plus sign in (5)):

\[
\Sigma = \left\{ \left( H - a(F) \right)^2 = -\frac{4}{27}b(F)^3 \right\} \subset \mathbb{R}^2(H, F).
\]

It has a cusp at the point \((H(P), F(P))\) that splits \( \Sigma \) into two smooth branches, \( \Sigma_{\text{ell}} \) and \( \Sigma_{\text{hyp}} \), corresponding to one-parameter families of elliptic and hyperbolic orbits. The bifurcation diagram for \( a(\lambda) = 0 \) and \( b(\lambda) = \lambda \) is shown on Fig. 3.

It can be easily seen (see details below) that \( \Sigma \) allows us to reconstruct both functions \( a(\lambda) \) and \( b(\lambda) \). We use this observation to prove

**Proposition 2.3.** Consider two parabolic singularities defined by functions \( H, F \) at a point \( P \) and \( \tilde{H}, \tilde{F} \) at a point \( \tilde{P} \) respectively. A map (local analytic diffeomorphism)

\[
\phi : \mathbb{R}^2(H, F) \to \mathbb{R}^2(\tilde{H}, \tilde{F})
\]

is liftable if and only if \( \phi \) transforms the bifurcation diagram of \( (H, F) \) to that of \( (\tilde{H}, \tilde{F}) \), i.e. \( \phi(\Sigma) = \tilde{\Sigma} \), together with its partition into elliptic and hyperbolic branches. In other words, the condition \( \phi(\Sigma) = \tilde{\Sigma} \) is necessary and sufficient for the existence of a local analytic diffeomorphism \( \Phi \) such that the diagram

\[
\begin{array}{ccc}
M^4 & \xrightarrow{\Phi} & \tilde{M}^4 \\
\downarrow{(H, F)} & & \downarrow{(\tilde{H}, \tilde{F})} \\
\mathbb{R}^2 & \xrightarrow{\phi} & \mathbb{R}^2
\end{array}
\]

is commutative.

**Proof.** The “only if” part is obvious.

Let us prove the “if” part. Denote \( \phi \circ (H, F) \) by \( (\tilde{H}, \tilde{F}) \). Clearly, \( \phi \) transforms the bifurcation diagram of \( (H, F) \) to that of \( (\tilde{H}, \tilde{F}) \), together with their partitions into elliptic and hyperbolic branches. Hence, the bifurcation diagram \( \tilde{\Sigma} \) of \( (\tilde{H}, \tilde{F}) \) coincides with the bifurcation diagram \( \Sigma \) of \( (H, F) \), together with its partition into elliptic and hyperbolic branches.

As shown above, under the condition that \( d\tilde{F}(\tilde{P}) \neq 0 \), the bifurcation diagram \( \tilde{\Sigma} \) of the mapping \( \tilde{F} = (\tilde{H}, \tilde{F}) : \tilde{M}^4 \to \mathbb{R}^2(h, f) \) is defined by

\[
\tilde{\Sigma} = \{(h, f) \in \mathbb{R}^2 \mid (h - \tilde{a}(f))^2 = -\frac{4}{27}\tilde{b}(f)^3\}
\]

for some functions \( \tilde{a}(\cdot) \) and \( \tilde{b}(\cdot) \) determined by the canonical form (5). Hence \( \tilde{\Sigma} \) lies entirely in a half-plane \( \{(h, f) \mid \tilde{b}(f) \leq 0\} \subset \mathbb{R}^2(h, f) \) bounded by a line \( \{f = \text{const}\} \) through the cusp point \((H(\tilde{P}), F(\tilde{P}))\). Since \( \tilde{\Sigma} = \tilde{\Sigma} \), we conclude that \( d\tilde{F}(\tilde{P}) \neq 0 \) as well.

By Lemma 2.2, there exist coordinates \( \hat{x}, \hat{y}, \hat{\lambda}, \phi \) in a neighborhood \( \hat{U} \) of \( P \) and coordinates \( \hat{x}, \hat{y}, \hat{\lambda}, \phi \) in a neighborhood \( U \) of \( P \) such that

\[
\hat{H} = \hat{x}^2 + \hat{y}^3 + \hat{b}(\hat{\lambda})\hat{y} + \hat{a}(\hat{\lambda}), \quad \hat{F} = \hat{\lambda},
\]

\[
\hat{H} = \hat{x}^2 + \hat{y}^3 + \hat{b}(\hat{\lambda})\hat{y} + \hat{a}(\hat{\lambda}), \quad \hat{F} = \hat{\lambda},
\]

\[
\hat{H} = \hat{x}^2 + \hat{y}^3 + \hat{b}(\hat{\lambda})\hat{y} + \hat{a}(\hat{\lambda}), \quad \hat{F} = \hat{\lambda},
\]
for some signs \( \tilde{\eta}, \hat{\eta} \in \{1, -1\} \). The elliptic and hyperbolic branches of \( \tilde{\Sigma} \) have the form
\[
\tilde{\Sigma}_{\text{ell}} = \left\{ (h, f) = \left( \hat{\eta} \left( \tilde{a}(f) - 2 \left( -\tilde{b}(f)/3 \right)^{3/2} \right), f \right) \bigg| \tilde{b}(f) < 0 \right\},
\]
\[
\tilde{\Sigma}_{\text{hyp}} = \left\{ (h, f) = \left( \hat{\eta} \left( \tilde{a}(f) + 2 \left( -\tilde{b}(f)/3 \right)^{3/2} \right), f \right) \bigg| \tilde{b}(f) < 0 \right\},
\]
in particular, \( \tilde{\eta} h - \tilde{a}(f) > 0 \) on \( \tilde{\Sigma}_{\text{hyp}} \) and \( < 0 \) on \( \tilde{\Sigma}_{\text{ell}} \). Since similar properties and formulae hold for the elliptic and hyperbolic branches of \( \hat{\Sigma} \), and moreover by construction \( \hat{\Sigma}_{\text{ell}} = \tilde{\Sigma}_{\text{ell}}, \hat{\Sigma}_{\text{hyp}} = \tilde{\Sigma}_{\text{hyp}} \), we obtain
\[
\hat{\eta} = \tilde{\eta}, \quad \hat{a}(\lambda) = \tilde{a}(\lambda), \quad \hat{b}(\lambda) = \tilde{b}(\lambda)
\]
where the equalities of functions hold in a half-neighbourhood \( \{ \lambda \mid \tilde{b}(\lambda) \leq 0 \} \) of the point \( \tilde{F}(\tilde{P}) \in \mathbb{R} \). Since all the functions are real-analytic at this point, these equalities hold in an entire neighbourhood.

Define a real-analytic diffeomorphism germ \( \Phi : (\tilde{U}, \tilde{P}) \to (\tilde{U}, \tilde{P}) \) given by the identity map in the local coordinates \((\tilde{x}, \tilde{y}, \tilde{\lambda}, \tilde{\varphi})\) and \((\hat{x}, \hat{y}, \hat{\lambda}, \hat{\varphi})\). By (7) and (8), \( \Phi \) transforms \((\hat{H}, \hat{F})\) to \((\tilde{H}, \tilde{F})\) so that we have the desired property \( \phi \circ (H, F) = (\tilde{H}, \tilde{F}) = (\hat{H}, \hat{F}) \circ \Phi \).

Proposition 2.3 implies the following

**Corollary 2.4.** Let \( P \) be a parabolic point for an integrable Hamiltonian system with the momentum map \( F = (H, F) : M^4 \to \mathbb{R}^2 \). Assume that the local bifurcation diagram \( \Sigma \subset \mathbb{R}^2(H, F) \) of \( F \) takes the standard form
\[
(9) \quad \Sigma = \left\{ \begin{array}{l} H^2 = -\frac{4}{27} F^3 \\ \text{with} \quad \Sigma_{\text{ell}} = \Sigma \cap \{ H < 0 \}, \quad \Sigma_{\text{hyp}} = \Sigma \cap \{ H > 0 \} \end{array} \right\}
\]
Then in a neighborhood of a parabolic point there exists a local coordinate system \((x, y, \lambda, \varphi)\) in which \( H = x^2 + y^3 + \lambda y \) and \( F = \lambda \).

**Proof.** It is sufficient to notice that the pair of functions \( \hat{H} = x^2 + y^3 + \lambda y, \hat{F} = \lambda \) define a parabolic singular point with the standard bifurcation diagram (9). According to Proposition 2.3 any other parabolic singularity with the same bifurcation diagram is fiberwise diffeomorphic to this simplest model, moreover, the map \( \phi : \mathbb{R}^2(H, F) \to \mathbb{R}^2(\hat{H}, \hat{F}) \) between the bases is defined by \( \hat{H} = H, \hat{F} = F \).

We are now able to complete the proof of Proposition 2.1. In view of Corollary 2.4, it is sufficient to show that by a suitable transformation (3) the bifurcation diagram, together with its partition into elliptic and hyperbolic branches, can be reduced to the standard form (9).

As shown above, for the original functions \( H \) and \( F \) the bifurcation diagram is defined by the equation
\[
\Sigma = \left\{ (H - a(F))^2 = -\frac{4}{27} b(F)^3 \right\}
\]
(here we assume that \( H \) in (5) comes with +).

Let \( F(P) = f_0 \) so that \( b(f_0) = 0 \) and \( b'(f_0) \neq 0 \), then we can represent \( b(\lambda) \) as \( b(\lambda) = (\lambda - f_0) c(\lambda) \) with \( c(f_0) \neq 0 \) and rewrite the equation for \( \Sigma \) in the form
\[
\left( \frac{H - a(F)}{c(F)^{3/2}} \right)^2 = -\eta_F^2 \frac{4}{27} (F - f_0)^3
\]
with \( \eta_F = c(f_0)/|c(f_0)| \) or, equivalently,
\[
\Sigma = \left\{ \tilde{H}^2 = -\frac{4}{27} \tilde{F}^3 \right\} \quad \text{with} \quad \Sigma_{\text{ell}} = \Sigma \cap \{ \tilde{H} < 0 \}, \quad \Sigma_{\text{hyp}} = \Sigma \cap \{ \tilde{H} > 0 \},
\]
for \( \tilde{H} = \frac{H - a(F)}{|c(F)|^{3/2}} \) and \( \tilde{F} = \eta_F (F - f_0) \), which coincides with (9) as required.

### 3. Symplectic Description of a Tubular Neighborhood of a Parabolic Orbit

Our next goal is to describe the symplectic structure \( \Omega \) near a parabolic orbit.

An important property of a parabolic orbit is the existence of a free Hamiltonian \( S^1 \)-action in its tubular neighborhood (N.T. Zung [28], cf. Kalashnikov [18]). In other words, without loss of generality we may assume that one of the commuting functions, say \( F \), generates this \( S^1 \)-action, i.e., the Hamiltonian flow of \( F \) is \( 2\pi \)-periodic. From the viewpoint of singularity theory, this means that in our case the parameter of the versal deformation is essentially unique and is given by the generator of the \( S^1 \)-action or, in slightly different terms, by the action variable related to the cycle in the first homology group of fibers that corresponds to this \( S^1 \)-action.
The latter interpretation, in particular, means that one of two action variables is a real-analytic function defined on the whole neighborhood \( U(\mathcal{L}_0) \) of \( \mathcal{L}_0 \) including singular fibers, where \( \mathcal{L}_0 \) denotes the singular fiber (cuspidal torus) containing the parabolic orbit \( \gamma_0 \). The action variable \( F \) is defined up to transformation \( F \to \pm F + \text{const} \), and we choose \( F \) in such a way that \( F(P) = 0 \) and the bifurcation diagram \( \Sigma \) is located in the domain \( \{ F \leq 0 \} \).

Basically, what we want to do next is to reduce our Hamiltonian system w.r.t. this action. We shall think of \( F \) as a parameter and denote it by \( \lambda \) as above. In particular, now we can choose a coordinate system \( x, y, \lambda, \varphi \) in a tubular neighborhood \( U(\gamma_0) \) of \( \gamma_0 \) in such a way that the Hamiltonian vector field of \( \lambda \) is \( \frac{\partial}{\partial \varphi} \). Since \( H \) commutes with \( F = \lambda \), we conclude that \( H = H(x, y, \lambda) \) and we are in the situation discussed in the previous section. If we are only interested in the symplectic topology of the fibration, we may assume without loss of generality that \( H \) is allowed and, using Corollary \ref{cor:2.1}, for a certain real-analytic function \( X(x, y, \lambda) \) with \( \frac{\partial X}{\partial x} > 0 \) and \( \tilde{\varphi} = \varphi + R(x, y, \lambda) \) for some real-analytic function \( \tilde{R}(x, y, \lambda) \). It follows from Proposition \ref{prop:3.1} that the function \( F \) is uniquely defined (being a generator of the \( S^1 \)-action), but \( H \) is not. However \( H \) cannot be chosen arbitrarily because the bifurcation diagram for \( F \) and \( H \) must be of a very special form (9). If this condition is fulfilled then \( H \) is allowed and, using Corollary \ref{cor:2.4}, we can modify Proposition \ref{prop:3.1} as follows.

**Proposition 3.1.** In a tubular neighborhood of a parabolic orbit \( \gamma_0 \) we can choose a coordinate system \( x, y, \lambda, \varphi \) (with \( \varphi \mod 2\pi \in \mathbb{R}/2\pi\mathbb{Z} \)) such that \( (x, y, \lambda, \varphi)|_{\gamma_0} = (0, 0, 0) \) and our singular Lagrangian fibration is given by two functions

\[
F = \lambda \quad \text{and} \quad H = x^2 + y^3 + \lambda y
\]

and the symplectic form

\[
\Omega = f(x, y, \lambda)dx \wedge dy + d\lambda \wedge d\varphi + d\lambda \wedge (P(x, y, \lambda)dx + Q(x, y, \lambda)dy) = 
\]

\[
= \omega_\lambda + d\lambda \wedge d\varphi + \text{ (additional terms)}.
\]

The form \( \omega_\lambda = f(x, y, \lambda)dx \wedge dy \) can be considered as the restriction of \( \Omega \) onto the common level of \( \lambda \) and \( \varphi \) (we assume that \( \varphi = 0 \) but \( \lambda \) varies and is considered as a parameter). The other interpretation of \( \omega_\lambda \) is that it is the one-parameter family of symplectic forms obtained from \( \Omega \) by the reduction w.r.t. the Hamiltonian \( S^1 \)-action (or, using old-style terminology, w.r.t. the cyclic variable \( \varphi \)).

**Remark 3.1.** Without loss of generality we may assume that \( f(x, y, \lambda) > 0 \) in (10). Indeed, in order for the latter property to be fulfilled, we only need to replace \( x \) with \(-x\) if necessary. We also notice that since \( \Omega \) is closed, formula (10) can be rewritten as

\[
\Omega = dX(x, y, \lambda) \wedge dy + d\lambda \wedge d\varphi
\]

for a certain real-analytic function \( X(x, y, \lambda) \) with \( \frac{\partial X}{\partial x} > 0 \) and \( \tilde{\varphi} = \varphi + R(x, y, \lambda) \) for some real-analytic function \( \tilde{R}(x, y, \lambda) \).

It follows from Proposition \ref{prop:3.1} that the function \( F \) is uniquely defined (being a generator of the \( S^1 \)-action), but \( H \) is not. However \( H \) cannot be chosen arbitrarily because the bifurcation diagram for \( F \) and \( H \) must be of a very special form (9). If this condition is fulfilled then \( H \) is allowed and, using Corollary \ref{cor:2.4}, we can modify Proposition \ref{prop:3.1} as follows.

**Proposition 3.2.** Consider a tubular neighborhood of a parabolic trajectory. Let \( H \) and \( F \) be two functions defining our fibration and satisfying the following conditions:

(i) the bifurcation diagram of \((H, F)\) is canonical, i.e., as in (9);

(ii) \( F \) is \( 2\pi \)-periodic, i.e., is a generator of a free Hamiltonian \( S^1 \)-action.

Then there exists a coordinate system \((x, y, \lambda, \varphi)\) as in Proposition \ref{prop:3.1}.

**Remark 3.2.** It follows from Proposition \ref{prop:3.1} that if we are given two integrable systems with parabolic trajectories, we can always find a fiberwise real-analytic diffeomorphism between their tubular neighborhoods that respects the \( S^1 \)-actions and corresponding periodic Hamiltonians. This means that without loss of generality we may assume that we are given just one single fibration defined by \( H \) and \( F \) having canonical form (4) with two different symplectic forms given by (10) (i.e. such that \( H \) and \( F \) commute and the Hamiltonian vector field of \( \lambda \) is \( \frac{\partial}{\partial \lambda} \)):
and
\[
\tilde{\Omega} = \tilde{\omega}_\lambda + d\lambda \wedge d\varphi + \text{ (additional terms)}.
\]

We still have two different integrable systems but after the above “pre-identification” they have many
common properties. Namely,

(i) They have a common local coordinate system \((x, y, \lambda, \varphi)\) from Proposition 3.1;
(ii) \(F = \lambda\) is a \(2\pi\)-periodic integral for both systems;
(iii) The \(S^1\)-actions defined by \(F\) for \(\Omega\) and \(\tilde{\Omega}\) coincide (i.e., \(X_F = \tilde{X}_F = \frac{\partial}{\partial \varphi}\) where \(X_F\) and \(\tilde{X}_F\) denote the Hamiltonian vector fields generated by \(F\) w.r.t. \(\Omega\) and \(\tilde{\Omega}\) respectively);
(iv) The bifurcation diagrams of these two systems coincide;
(v) The orientations and coorientations of the parabolic trajectory \(\gamma(t) = (0, 0, \varphi = t)\) induced by \(\Omega\) and \(\tilde{\Omega}\) coincide (see Section 5, Theorem 5.4).

We need to find out whether \(\Omega\) can be transformed to \(\tilde{\Omega}\) by a suitable fiberwise diffeomorphism \(\Phi\).
First, we impose a stronger condition on \(\Phi\) by requiring that \(\Phi\) preserves not only the fibration but also
each particular fiber, i.e. the functions \(H\) forbidden, i.e. \(\Phi\) induces the identity map on the base of the fibration.

The following statement reduces this 4-dim problem for \(\Omega\) and \(\tilde{\Omega}\) to a similar problem for the reduced
forms \(\omega_\lambda\) and \(\tilde{\omega}_\lambda\).

Consider the singular fibration defined by the functions \(H = x^2 + y^3 + 4y\) and \(F = \lambda\). This fibration is obviously Lagrangian w.r.t. any of the symplectic structures (11) and (12) in a neighborhood of the parabolic orbit \(\gamma_0 = \{x = y = \lambda = 0\}\).

**Proposition 3.3.** The following two statements are equivalent.

(i) In a tubular neighborhood of the parabolic orbit \(\gamma_0\) there is a (real-analytic) diffeomorphism \(\Phi\) such that

- \(\Phi\) preserves \(H\) and \(F\);
- \(\Phi^*(\tilde{\Omega}) = \Omega\).

(ii) There exists a one-parameter family of local diffeomorphisms \(\psi_\lambda(x, y)\) (real-analytic in \(x, y\) and \(\lambda\)) leaving fixed the origin in \(\mathbb{R}^2(x, y)\) at \(\lambda = 0\) and such that, for each \(\lambda \in \mathbb{R}\) close enough to 0,

- \(\psi_\lambda\) preserves \(H(x, y, \lambda)\);
- \(\psi_\lambda^*(\tilde{\omega}_\lambda) = \omega_\lambda\).

**Proof.** The fact that (i) implies (ii) is almost obvious. Indeed, since \(\Omega\) and \(\tilde{\Omega}\) are of quite special form, \(\Phi^*(\tilde{\Omega}) = \Omega\) and \(F = \lambda\) is preserved, then in local coordinates \(x, y, \lambda, \varphi\), the diffeomorphism \(\Phi\) takes the following form:

\[
\begin{align*}
\tilde{x} &= \tilde{x}(x, y, \lambda), \\
\tilde{y} &= \tilde{g}(x, y, \lambda), \\
\tilde{\lambda} &= \lambda, \\
\tilde{\varphi} &= \varphi + R(x, y, \lambda).
\end{align*}
\]

If we consider the first two functions as a family of diffeomorphisms \(\psi_\lambda(x, y)\), then we will immediately see that (ii) holds. Since \(\Phi\) preserves \(H\) and \(F\), it leaves invariant the set of such points \((x, y, \lambda, \varphi)\) that

\[
dH(x, y, \lambda, \varphi) = dF(x, y, \lambda, \varphi)
\]

are proportional. But for \(\lambda = 0\) this set coincides with \(\gamma_0\), so \(\Phi\) maps \(\gamma_0\) to itself. Therefore \(\psi_0(0, 0) = (0, 0)\).

The proof of the converse statement consists of two steps. Assuming that \(\psi_\lambda(x, y)\) satisfies the conditions from (ii), we define \(\Phi_1\) as follows:

\[
\begin{align*}
(\tilde{x}, \tilde{y}) &= \psi_\lambda(x, y), \\
\tilde{\lambda} &= \lambda, \\
\tilde{\varphi} &= \varphi.
\end{align*}
\]

It is easily checked that, for this \(\Phi_1\), the symplectic forms \(\Phi_1^*(\tilde{\Omega})\) and \(\Omega\) coincide up to additional terms, that is

\[
\Phi_1^*(\tilde{\Omega}) - \Omega = d\lambda \wedge (P(x, y, \lambda)dx + Q(x, y, \lambda)dy).
\]

Hence, our goal is to show that these additional terms do not play any essential role and can be killed by
an appropriate shift \(\varphi \mapsto \varphi - R(x, y, \lambda)\) (without changing the other coordinates). In other words, we need to find \(R(x, y, \lambda)\) such that

\[
d\lambda \wedge dR(x, y, \lambda) = d\lambda \wedge (P(x, y, \lambda)dx + Q(x, y, \lambda)dy).
\]

The existence of such a
function follows immediately from the closedness of the form (13). Finally, defining $\Phi$ as the composition of $\Phi_1$ and the above shift, we get $\Phi^*(\tilde{\Omega}) = \Phi_1^*(\tilde{\Omega}) - d\lambda \wedge dR(x, y, \lambda) = \Omega$ due to (13).

It remains to notice that, since $\psi_0(0, 0) = (0, 0)$ and $\gamma_0 = \{x = y = \lambda = 0\}$, we have $\Phi(\gamma_0) = \gamma_0$, thus $\Phi$ is defined in a neighborhood of $\gamma_0$ as required. □

Our next observation is that symplectic invariants do exist, in other words, the desired map $\Phi$ (or, equivalently, the family $\psi_\lambda$) may not exist. Moreover, the existence of just one map $\psi_0$ implies rather strong condition. To show this, we treat the case $\lambda = 0$ in detail.

4. The case $\lambda = 0$: one degree of freedom problem

In this Section, for notational convenience, we use a different sign in the definition of $H$, namely, we set $H = y^3 - x^2$. Consider two symplectic forms $\omega$ and $\tilde{\omega}$ (in Section 3, these forms were denoted by $\omega_0$ and $\tilde{\omega}_0$ but now $\lambda = 0$ is fixed and we may temporarily forget about parameter $\lambda$ in $\omega_\lambda$). We want to know necessary and sufficient conditions for the existence of a local diffeomorphism $\psi$ satisfying $\psi^*\tilde{\omega} = \omega$ and (two versions):

- either preserving $H$ (strong condition);
- or preserving the fibration defined by $H$ (weaker condition), more formally, $\psi^*(H) = h(H)$ where $h(H)$ is real-analytic and $h'(0) \neq 0$.

\[ \omega = \alpha(H) \, dx \wedge dy + \beta(H) \, y \, dx \wedge dy + dH \wedge d\eta \]

for some holomorphic germ $\eta(x, y)$, and unique $\alpha, \beta \in \mathbb{C}\{H\}$.

Remark 4.1. If $\omega$ is symplectic, then $\alpha(0) \neq 0$.

In our case we are dealing with real objects $\omega$ and $H$, in this case $\alpha(H), \beta(H)$ are real-analytic, and $\eta(x, y)$ can be chosen to be real-analytic, as can be shown by taking the real part of Equation (14).

Choose two one-dimensional cross-sections $N_1, N_2$ to the fibration defined by $H = y^3 - x^2$ as shown in Fig.1. Each non-singular leaf $\tau_H$ of this fibration (with a given value of $H$) now will be interpreted as a trajectory of the Hamiltonian vector field $X_H = \omega^{-1}(dH)$ with respect to the symplectic form $\omega$. For each trajectory $\tau_H$ we can measure the passage time $\Pi(H)$ from $N_1$ to $N_2$. This function can be expressed as

\[ \Pi(H) = \int_{N_1}^{N_2} \frac{\omega}{dH} \]

(integral taken along the trajectory $\tau_H$) where $\omega/dH$ is the Gelfand-Leray form associated to the pair $(\omega, H)$, i.e., any 1-form $\gamma$ defined in the region $dH \neq 0$ and such that $dH \wedge \gamma = \omega$ (the form $\gamma$ is not uniquely defined, but its restriction to the level-sets $H = \text{const}$ is unique).
We can similarly consider the area function \( \text{area}(H) \) defined as the integral of \( \omega \) over the subset of \( \{ 0 \leq H(x, y) \leq H \} \) bounded by the sections \( N_1, N_2 \). As a consequence of Fubini’s theorem, one has

\[
\frac{d\text{area}(H)}{dH} = \Pi(H).
\]

Clearly, \( \Pi(H) \) is a real-analytic function defined for all (small) \( H \). As \( H \) tends to 0, the passage time \( \Pi(H) \) tends to infinity and it is natural to look at the asymptotic behaviour of \( \Pi(H) \) at zero.

**Lemma 4.2.** The function \( \Pi(H) \) for \( H > 0 \) can be written as

\[
\Pi(H) = a(H)H^{-1/6} + b(H)H^{1/6} + c(H), \quad H > 0,
\]

where \( a, b, c \in \mathbb{R}\{H\} \). Moreover, \( a(H) = C_0 \alpha(H) \) and \( b(H) = C_1 \beta(H) \) for some non-zero constants \( C_0, C_1 \in \mathbb{R} \), with \( C_0 > 0 \) and \( C_1 < 0 \).

Before proving the lemma, we give some remarks:

- The functions in this representations are uniquely defined, i.e., if
  \[
  a(H)H^{-1/6} + b(H)H^{1/6} + c(H) = \tilde{a}(H)H^{-1/6} + \tilde{b}(H)H^{1/6} + \tilde{c}(H),
  \]
  then \( a(H) = \tilde{a}(H), b(H) = \tilde{b}(H) \) and \( c(H) = \tilde{c}(H) \).

- If we change the sections \( N_1 \) and \( N_2 \) by a deformaton in the class of such sections, then the function \( \Pi(H) \) changes by adding a certain analytic function, given by the passage time between the old and the new sections. However, if we replace \( N_1 \) and \( N_2 \) by each other, then the function \( \Pi(H) \) will be replaced by \(-\Pi(H)\). This shows that the functions \( a(H) \) and \( b(H) \) (up to multiplying with \(-1\) simultaneously) do not depend on the choice of the cross-sections \( N_1 \) and \( N_2 \). Since we are working with a symplectic form, we have \( a(0) \neq 0 \) and \( a(0) \neq 0 \), and we can be more specific: the functions \( a(H) \) and \( b(H) \) with \( a(0) > 0 \) do not depend on the choice of the cross-sections \( N_1 \) and \( N_2 \).

- In a similar way, we can define the functions \( \tilde{a}, \tilde{b}, \tilde{c} \) for the second symplectic structure \( \tilde{\omega} \). If \( \psi \) preserves \( H \) and transforms \( \omega \) to \( \tilde{\omega} \), then the Hamiltonian vector field \( X_H \) will be transformed to the Hamiltonian vector field \( \tilde{X}_H = \tilde{\omega}^{-1}(dH) \) (with the same Hamiltonian \( H \)). Since \( \psi \) does not preserve the cross-sections \( N_1 \) and \( N_2 \), the passage time \( \Pi(H) \) will, in general, differ from \( \Pi(H) \) by adding some analytic functions (and, possibly, by multiplying with \(-1\)), which shows that the functions \( a(H) \) and \( b(H) \) with \( a(0) > 0 \) remain invariant under \( \psi \), i.e. \( a(H) = \tilde{a}(H), b(H) = \tilde{b}(H) \), provided that \( \tilde{a}(0) > 0 \) too. In other words, \( a(H) \) and \( b(H) \) with \( a(0) > 0 \) are symplectic invariants (under the condition that \( \psi \) preserves \( H \)).

- It is easy to give an example of two symplectic structures producing two different pairs of functions \( a \) and \( b \) in the asymptotic decomposition (17).

**Proof of Lemma 4.2.** Consider the decomposition (14). Taking the integral of the Gelfand-Leray form we get:

\[
\Pi(H) = a(H) \int_{N_1}^{N_2} \frac{dx \wedge dy}{dH} + \beta(H) \int_{N_1}^{N_2} \frac{ydx \wedge dy}{dH} + N_2^* \eta(H) - N_1^* \eta(H)
\]

(the coefficients can be taken outside of the integral, since we integrate along a trajectory \( \tau_H \) where \( H \) is constant). The last two terms give a real-analytic contribution. To finish the proof it is sufficient to show that, for \( H > 0 \)

\[
\int_{N_1}^{N_2} \frac{dx \wedge dy}{dH} \in \mathbb{R}\{H\}, \quad \int_{N_1}^{N_2} \frac{ydx \wedge dy}{dH} - C_1 H^{1/6} \in \mathbb{R}\{H\},
\]

for some non-zero real constants \( C_0, C_1 \), so that \( a(H) = C_0 \alpha(H) \) and \( b(H) = C_1 \beta(H) \). We can assume that \( N_1 = \{ x = 1 \} \) and \( N_2 = \{ x = -1 \} \). We have

\[
\frac{y^j dx \wedge dy}{dH} = -\frac{dx}{3y^{2j-3}}, \quad j = 0, 1.
\]

Hence, we are reduced to compute, for \( j = 0, 1 \), the integral:

\[
J_j(H) = \frac{1}{3} \int_{-1}^{1} y(H, x)^{j-2} dx = \frac{2}{3} \int_{0}^{1} (H + x^2)^{j-2} dx
\]

\[
= \frac{2}{3} H^{j-2} \int_{0}^{1} (1 + x^2)^{j-2} dx = \frac{1}{3} H^{j-2} \int_{0}^{1} t^{j-1} (1 + \frac{1}{t^2})^{j-2} dt
\]

\[
= \frac{2}{3} H^{j-2} F \left( \frac{j}{4}, \frac{1}{2}, \frac{3}{2}; -\frac{1}{H} \right)
\]
where \( F(p,q,r;z) \) is the hypergeometric function. In this case we can use the connection formula ([23, Eq. (9.5.9)])

\[
F(p,q,r;z) = c_1(-z)^{-p}F(p,1+p-r,1+p-q,1/z) + c_2(-z)^{-q}F(q,1+q-r,1+q-p,1/z)
\]

where

\[
c_1 = \frac{\Gamma(r)\Gamma(q-p)}{\Gamma(r-p)\Gamma(q)} \quad c_2 = \frac{\Gamma(r)\Gamma(p-q)}{\Gamma(r-q)\Gamma(p)}
\]

This gives:

\[
J_j(H) = \frac{2}{3} H^{3/2} \left( c_1 H^{2+2j} F(2+j, \frac{1}{3}, \frac{1-2j}{6}, -H) + c_2 H^{1/2} F(\frac{3}{2}, 0, \frac{5+2j}{6}, -H) \right)
\]

\[
= \frac{2}{3} c_1 F(\frac{2-j}{3}, \frac{1-2j}{6}, \frac{7-2j}{6}, -H) + \frac{2}{3} c_2 H^{2j+1/6}
\]

\[
= C_j H^{2j+1} + d_j(H), \quad d_j \in \mathbb{R}\{H\},
\]

where \( C_0 = \frac{\sqrt{\pi}}{3} \frac{\Gamma((1/6))}{\Gamma((2/3))} \) and \( C_1 = \frac{\sqrt{\pi}}{3} \frac{\Gamma(-1/6)}{\Gamma(1/3)} \). This proves (18) as required. \( \square \)

For \( r \notin \mathbb{Q} \), consider the operator \( \phi_r : \mathbb{R}\{H\} \rightarrow \mathbb{R}\{H\} \) defined by \( \phi_r : A(H) \mapsto A'(H)H + rA(H) \). If \( r \notin \mathbb{Z} \) then \( \phi_r \) is bijective.

**Corollary 4.3.** The function \( \text{area}(H) \) for \( H \geq 0 \) can be written as

\[
\text{area}(H) = A(H)H^{5/6} + B(H)H^{7/6} + C(H), \quad H \geq 0,
\]

where \( A, B, C \in \mathbb{R}\{H\} \) are the unique real-analytic germs such that

\[
a(H) = A'(H)H + \frac{3}{5} A(H), \quad b(H) = B'(H)H + \frac{3}{7} B(H), \quad c(H) = C'(H), \quad C(0) = 0,
\]

in other words \( A = \phi_{5/6}^{-1}(a) \), \( B = \phi_{7/6}^{-1}(b) \). \( \square \)

**Theorem 4.4.** Let \( \omega, \tilde{\omega} \) be two real-analytic symplectic forms such that \( \omega - \tilde{\omega} = dH \wedge d\eta \) for some real-analytic function germ \( \eta(x,y) \) at \( 0 \in \mathbb{R}^2 \). Then there is a local diffeomorphism \( \psi \) at \( 0 \in \mathbb{R}^2 \) such that \( \psi^*H = H \) and \( \psi^*\omega = \omega \).

**Proof.** We adapt the proof of [14, Theorem 2.1]. Put \( \omega_t = \omega + t(\tilde{\omega} - \omega) \). In a neighborhood of zero, the forms \( \omega_t \), for \( t \in [0,1] \), are also non-degenerate, indeed the equation \( \omega - \tilde{\omega} = dH \wedge d\eta \) implies that the two forms have the same sign/orientation at zero and near zero. Since \( \omega_t \) is a convex combination of functions with the same sign, it will also be non-zero in a neighborhood of zero. Define a real-analytic time-dependent vector field \( X_t \) by

\[
i_{X_t} \omega_t = -\eta dH.
\]

Let \( \phi_t \) be the flow generated by such \( X_t \), we can integrate it for \( t \in [0,1] \). Notice that

\[
L_{X_t} \omega_t = i_{X_t} d\omega_t + d i_{X_t} \omega_t = dH \wedge d\eta = \omega - \tilde{\omega},
\]

therefore

\[
\frac{d}{dt} \phi_t^* \omega_t = \phi_t^* \left( L_{X_t} \omega_t + \frac{d}{dt} \omega_t \right) = 0,
\]

so that \( \phi_t^* \tilde{\omega} = \omega \). Moreover \( L_{X_t} H = 0 \), because of the equality:

\[
0 = i_{X_t} (dH \wedge \omega_t) = (i_{X_t} dH)\omega_t + dH \wedge i_{X_t} \omega_t = (L_{X_t} H)\omega_t + dH \wedge i_{X_t} \omega_t = (L_{X_t} H)\omega_t,
\]

and using \( \omega_t \neq 0 \). This means that \( H \circ \phi_t = H \). Finally take \( \psi = \phi_1 \). \( \square \)

In the rest of the Section, \( \tilde{\alpha}, \tilde{\beta}, \tilde{a}, \tilde{b}, \tilde{A}, \tilde{B} \) and \( \tilde{\Pi} \) will be used for natural analogs of functions \( \alpha, \beta, a, b, A, B \) and \( \Pi \) introduced for \( \tilde{\omega} \). For the reasons explained in the second and third remarks below Lemma 4.2, we will consider symplectic forms inducing a fixed orientation. In this regard we can consider, without loss of generality, only symplectic forms \( \omega \) with \( \alpha(0) > 0 \) (similarly \( \tilde{\alpha}(0) > 0 \) for \( \tilde{\omega} \)). Such symplectic forms are said to be positively-oriented.

In the above setting and notation, Theorem 4.4, Lemma 4.2 (and the remarks below it) and Corollary 4.3 imply two corollaries.

**Corollary 4.5.** Let \( \omega, \tilde{\omega} \) be positively-oriented symplectic forms. An \( H \)-preserving map \( \psi \) such that \( \psi^*\tilde{\omega} = \omega \) exists, if and only if the following conditions hold:

\[
\alpha(H) = \tilde{\alpha}(H) \quad \text{and} \quad \beta(H) = \tilde{\beta}(H)
\]

or, equivalently, \( a(H) = \tilde{a}(H) \) and \( b(H) = \tilde{b}(H) \) or \( A(H) = \tilde{A}(H) \) and \( B(H) = \tilde{B}(H) \). \( \square \)
Corollary 4.6. Let $\omega, \tilde{\omega}$ be positively-oriented symplectic forms. An $H$-preserving map $\psi$ such that $\psi^*\tilde{\omega} = \omega$ exists if and only if $\Pi(H) - \tilde{\Pi}(H)$, which is defined on $\{H > 0\}$, extends to a real-analytic function in a neighborhood of $H = 0$. □

We can also reformulate these results in terms of normal forms.

Proposition 4.7. For $H = y^3 - x^2$ and $\omega = f(x,y)dx \wedge dy$ there is a real-analytic local coordinate system $u, v$ and germs $\alpha, \beta \in \mathbb{R}\{H\}$ such that

$$H = v^3 - u^2 \quad \text{and} \quad \omega_0 = \alpha(H) \cdot du \wedge dv + \beta(H) \cdot v \, du \wedge dv.$$  

For positively-oriented symplectic forms, the functions $\alpha(H)$ and $\beta(H)$ are uniquely defined (the coordinates $u,v$ are not). □

Let us now see what happens if $\psi$ does not preserve $H$, but transforms it to a function of the form $h(H)$, $h'(0) \neq 0$ (in fact $h'(0) > 0$). Let $\omega, \tilde{\omega}$ be positively-oriented symplectic forms. We consider necessary and sufficient conditions for the existence of a local diffeomorphism $\psi$ such that $\psi^*\tilde{\omega} = \omega$ and $\psi^*H = h(H)$ with $h'(0) > 0$, i.e. a local symplectomorphism $\psi$ making the following diagram commutative:

$$\begin{array}{ccc}
\mathbb{R}^2, 0 & \xrightarrow{\psi} & \mathbb{R}^2, 0 \\
\downarrow H & & \downarrow H \\
(\mathbb{R}, 0) & \xrightarrow{h} & (\mathbb{R}, 0).
\end{array}$$

We first notice that any local diffeomorphism germ $H \mapsto h(H)$ at 0 with $h'(0) > 0$ is liftable. In other words we have

Lemma 4.8. For any real-analytic map $h : (\mathbb{R}, 0) \to (\mathbb{R}, 0)$ with $h'(0) > 0$ there exists $\psi : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0)$ (local real-analytic diffeomorphism) such that

$$\psi(H(x,y)) = h(H(x,y)).$$

Proof. Let $h(H) = H \cdot g(H)$. Define $\psi(x,y) = r_h(x,y) := (g(H(x,y))^{1/2}x, g(H(x,y))^{1/3}y)$, then

$$H(r_h(x,y)) = g(H(x,y))H(x,y) = h(H(x,y)).$$  □

If $h(H)$ is given, then we can easily find the relations between the functions $\alpha, \beta, a, b, A, B$ and their natural analogs $\tilde{\alpha}, \tilde{\beta}, \tilde{a}, \tilde{b}, \tilde{A}, \tilde{B}$ for $\tilde{\omega}$. These relations do not depend on the lifting of $h$. Straightforward computation (see [4]) gives

Lemma 4.9. Suppose there exists $\psi$ such that $\psi^*\tilde{\omega} = \omega$ and $\psi^*H = h(H)$ with $h(H) = H \cdot g(H)$, $g(0) > 0$. Then we have the following relations:

i)

$$\begin{cases}
A(H) = g(H)^{5/6}\tilde{A}(h(H)), \\
B(H) = g(H)^{7/6}\tilde{B}(h(H)),
\end{cases}$$

ii)

$$\begin{cases}
\alpha(H) = g(H)^{-1/6}(g'(H)H + g(H))\tilde{\alpha}(h(H)), \\
\beta(H) = g(H)^{1/6}(g'(H)H + g(H))\tilde{\beta}(h(H)),
\end{cases}$$

iii)

$$\begin{cases}
\tilde{a}(H) = g(H)^{-1/6}(g'(H)H + g(H))\tilde{a}(h(H)), \\
\tilde{b}(H) = g(H)^{1/6}(g'(H)H + g(H))\tilde{b}(h(H)).
\end{cases}$$

Combining these two lemmas and Corollary 4.5, we come to the following criterion.

Proposition 4.10. Consider two positively-oriented symplectic forms $\omega, \tilde{\omega}$. The following conditions are equivalent:

• there exists a real-analytic map $h : (\mathbb{R}, 0) \to (\mathbb{R}, 0)$ such that $h(H) = H \cdot g(H)$ with $g(0) > 0$ for which one of the three relations (i), (ii), (iii) from Lemma 4.9 is satisfied;

• there exists a local diffeomorphism $\psi : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0)$ such that $\psi^*\tilde{\omega} = \omega$ and $\psi^*H = h(H)$ with $h'(0) > 0$. 
Proof. We assume (ii) is satisfied, the other two cases are equivalent. Consider the map \( r_b \) (lifting of \( h \)) from the proof of Lemma 4.8. It satisfies \( r_b^* H = h(H) \) and transforms \( \tilde{\omega} \) to some form \( \tilde{\omega} = r_b^* \tilde{\omega} \). Therefore by Lemma 4.9
\[
\tilde{\alpha}(H) = g^{-1/6}(H) (g'(H) H + g(H)) \tilde{\alpha}(h(H)) = \alpha(H),
\]
\[
\tilde{\beta}(H) = g^{1/6}(H) (g'(H) H + g(H)) \tilde{\beta}(h(H)) = \beta(H).
\]
Applying Corollary 4.5 for \( \omega \) and \( \tilde{\omega} \), we can find an \( H \)-preserving diffeomorphism \( \phi \) such that \( \phi^* \tilde{\omega} = \omega \).

In conclusion, \( \psi = r_h \circ \phi \) is the map we are looking for. The converse statement is equivalent to Lemma 4.9. \( \Box \)

Finally, we use Proposition 4.10 to get a well-defined canonical form for the symplectic structure \( \omega \) and hence to describe symplectic invariants of cusp singularities for Hamiltonian systems with one degree of freedom.

Proposition 4.11. A real-analytic singular Lagrangian fibration with one degree of freedom is symplectomorphic, in a neighborhood of a cusp singularity, to one of the non-symplectomorphic fibrations given by
\[
H = y^3 - x^2, \quad \omega_{\text{canon}} = dx \wedge dy + f(y^3 - x^2) \cdot dy \wedge dx,
\]
where \( f \) is a real-analytic function. Equivalently, in a neighborhood of a cusp singularity we can always find local coordinates \( x \) and \( y \) such that the fibration is defined by the function \( H = y^3 - x^2 \) and the symplectic structure takes the form \( \omega_{\text{canon}} = dx \wedge dy + f(H) \cdot dy \wedge dx \). Such coordinates are not unique, but the real-analytic function \( f(H) \) is well defined, i.e., does not depend on the choice of \( x \) and \( y \).

Proof. Taking into account Proposition 4.10, it suffices to prove that by a suitable transformation \( H \mapsto h(H) = H \cdot g(H) \) the invariant \( \alpha(H) \) can be reduced to 1.

Without loss of generality we assume that \( \omega \) is positively oriented and therefore \( \alpha(0) > 0 \). It follows from Lemma 4.2 and Corollary 4.3 that \( A(0) > 0 \) as well. Setting \( g(H) = \left( \frac{5}{6} C_0^{-1} A(H) \right)^{6/5} \) where \( C_0 > 0 \) is the constant from Lemma 4.2, and \( \tilde{\omega} = (r_b^{-1})^* \omega \), we obtain from Lemma 4.9 that \( \tilde{\alpha}(H) = \frac{5}{6} C_0 \). With this choice of \( h(H) = H \cdot g(H) \), we have \( A(H) = \frac{5}{6} C_0 g(H)^{6/5} \), therefore by Corollary 4.3
\[
\alpha(H) = A'(H) H + \frac{5}{6} A(H)
\]
\[
= C_0 g(H)^{-1/5} (g'(H) H + g(H)),
\]
so that \( \tilde{\alpha}(H) = C_0 \) and \( \tilde{\alpha}(H) = C_0^{-1} \tilde{\alpha}(H) = 1 \). \( \Box \)

This proposition says that as a complete symplectic invariant of a cusp singular fibration with one degree of freedom we may consider one (real-analytic) function in one variable. Since such a fibration appears as a symplectic reduction of the Lagrangian fibration near a parabolic orbit (for \( \lambda = 0 \)), we conclude that parabolic orbits possess non-trivial symplectic invariants and the next section is aimed at describing “all of them”.

5. Parametric version

Our next step is a parametric version of the above construction. We now assume that \( H \) depends on \( \lambda \) as a parameter:
\[
H(x, y, \lambda) = H_\lambda(x, y) = x^2 + y^3 + \lambda y
\]
and for each value of \( \lambda \) we consider a symplectic structure \( \omega_\lambda = f(x, y, \lambda) dx \wedge dy, \ f > 0 \).

We first give necessary and sufficient conditions for the existence of a family of maps \( \psi_\lambda \) from Proposition 3.3.

Following the same idea as before, we choose two 2-dimensional sections \( \mathcal{N}_1 \) and \( \mathcal{N}_2 \) analogous to the above sections \( N_1 \) and \( N_2 \) (but now for all values of \( \lambda \)) and define the passage time
\[
\Pi(H, \lambda) = \int_{\mathcal{N}_1(H, \lambda)} \omega_\lambda \cdot dH_\lambda
\]
for each trajectory with parameters \( H \) and \( \lambda \), \( (H, \lambda) \notin \Sigma_{\text{hyp}} \), see Fig. 2. Also we see that for each \( \lambda < 0 \) we have a family of closed trajectories also parametrised by \( H \) and \( \lambda \). Let us denote by \( \Pi_\circ(H, \lambda) \) the period of these trajectories\(^1\). We can compute these functions for both forms \( \omega_\lambda \) and \( \tilde{\omega}_\lambda \). For \( \tilde{\omega}_\lambda \), we denote them by \( \tilde{\Pi}(H, \lambda) \) and \( \tilde{\Pi}_\circ(H, \lambda) \).

\(^1\)Alternatively we may compute the area \( \text{area}_b(H, \lambda) = 2\pi I_\circ(H, \lambda) \) enclosed by such a trajectory. This function can be understood as the action variable corresponding to this family of closed cycles. Notice that \( \Pi_\circ \) and \( I_\circ \) are related by differentiation: \( \Pi_\circ(H, \lambda) = 2\pi \int \frac{\partial}{\partial H} I_\circ(H, \lambda), \) comp. (16).

Figure 2. Two cross-sections $\mathcal{N}_1, \mathcal{N}_2$ to the fibration near a parabolic orbit

**Proposition 5.1.** A family of local diffeomorphisms $\psi_\lambda$ from Proposition 3.3 exists if and only if

(i) $\Pi(H, \lambda) - \tilde{\Pi}(H, \lambda)$ extends to a real-analytic function in a neighborhood of the point $H = 0, \lambda = 0$,

(ii) $\Pi_\lambda(H, \lambda) = \Pi_\lambda(H, \lambda)$.

**Proof.** We need to justify the “if” part only. First of all we notice that, for each $\lambda$ (if we consider each slice $\{\lambda = \text{const}\}$ separately), a map $\psi_\lambda$ exists. Indeed, for $\lambda > 0$, there are no obstructions for the existence of $\psi_\lambda$ at all, since our fibration is regular. For $\lambda = 0$, the existence of $\psi_\lambda$ was proved in Corollary 4.6. As for $\lambda < 0$, this property follows from non-degeneracy of singular points (see [10]).

We only need to “combine” all these maps into one single $\Psi(x, y, \lambda) = \psi_\lambda(x, y)$ in such a way that $\Psi$ is real-analytic with respect to all variables (including $\lambda$).

To that end, we notice first of all that the maps $\psi_\lambda$ can be chosen in such a way that each section $\mathcal{N}_{1, \lambda} = \{(x, y, \lambda) \in \mathcal{N}_1$ with $\lambda$ fixed} (i.e. the intersection of $\mathcal{N}_1$ with the corresponding $\lambda$-slice) is mapped to itself, i.e., $\psi_\lambda|\mathcal{N}_{1, \lambda} = \text{id}$. This choice (of the initial data) makes our construction unique. In other words, we may assume without loss of generality that $\Psi$ leaves $\mathcal{N}_1$ fixed.

Let $\sigma^t$ and $\tilde{\sigma}^t$ denote the Hamiltonian flows of $H_\lambda$ w.r.t. $\omega_\lambda$ and $\tilde{\omega}_\lambda$ respectively. Since $H$ is preserved and $\psi_\lambda^\ast(\tilde{\omega}_\lambda) = \omega_\lambda$, we conclude that $\psi_\lambda$ sends the Hamiltonian flow of $H$ w.r.t. $\omega_\lambda$ to that w.r.t. $\tilde{\omega}_\lambda$, i.e., the following relation holds

$$\psi_\lambda \circ \sigma^t = \tilde{\sigma}^t \circ \psi_\lambda.$$  

This relation implies a simple “explicit” formula for $\psi_\lambda$ (for those points $Q$ which can be obtained from $\mathcal{N}_1$ by shifting along the flow $\sigma^t$). Namely, let $Q = \sigma^{t(Q)}(Q_0)$ with $Q_0 \in \mathcal{N}_1$. Then applying the above relation to the point $Q$ with $t = -t(Q)$ we get

$$\psi_\lambda \circ \sigma^{-t(Q)}(Q) = \tilde{\sigma}^{-t(Q)} \circ \psi_\lambda(Q)$$

or, equivalently,

$$\psi_\lambda(Q) = \tilde{\sigma}^{t(Q)} \circ \psi_\lambda \circ \sigma^{-t(Q)}(Q)$$

and, using that $\psi_\lambda \circ \sigma^{-t(Q)}(Q) = \psi_\lambda(Q_0) = Q_0 = \sigma^{-t(Q)}(Q)$, we finally get:

$$\psi_\lambda(Q) = \tilde{\sigma}^{t(Q)} \circ \sigma^{-t(Q)}(Q),$$

where the time $t(Q)$ is chosen in such a way that $\sigma^{-t(Q)}(Q) \in \mathcal{N}_1$. Notice that the family $\psi_\lambda$ so defined automatically satisfies the required conditions (ii) from Proposition 3.3 and is locally analytic w.r.t. all the variables (including $\lambda$) everywhere where it makes sense. The problem, however, is that (21) works neither at the singular points nor at the points lying on “small” closed trajectories that appear for $\lambda < 0$ (the reason is obvious: the Hamiltonian flow $\sigma^t$ starting from $\mathcal{N}_1$ does not reach them).

Below, we will use a slightly different version of formula (21). Notice that $Q$ can also be obtained from $Q_0 \in \mathcal{N}_1$ by shifting along the other Hamiltonian flow $\tilde{\sigma}^t$, that is, $Q = \tilde{\sigma}^{t(Q)}(Q_0)$ for some $t(Q) \in \mathbb{R}$.
Hence,
\[ \psi_\lambda(Q) = \tilde{\sigma}^{i(Q)} \circ \sigma^{-i(Q)}(Q) = \tilde{\sigma}^{i(Q)} \circ \tilde{\sigma}^{-i(Q)}(Q) = \tilde{\sigma}^{i(Q)}(Q) \circ \tilde{\sigma}^{-i(Q)}(Q) = \tilde{\sigma}^{i(Q)}(Q), \]

or, finally,
\[ \psi_\lambda(Q) = \tilde{\sigma}(Q), \quad \text{where } r(Q) = t(Q) - i(Q). \]

Our goal is to show that (22) extends to a neighborhood of the parabolic point up to a well defined real-analytic map in the sense of all the variables \( x, y \) and \( \lambda \).

To that end, we use a “complexification trick”. Since all the objects under consideration are real-analytic we can naturally complexify them, that is, we may think of \( x, y, \lambda \) as complex variables, \( H \) and \( F \) as complex functions, \( \omega \) and \( \tilde{\omega} \) as complex symplectic forms, etc. We also assume that the section \( \mathcal{N}_1 \) is given by an analytic equation like \( f(x, y) = 0 \), so that the same equation defines a (local) complex hypersurface that is transversal to all complexified leaves \( L_{\varepsilon_1, \varepsilon_2} = \{ H = \varepsilon_1, F = \varepsilon_2 \}, (\varepsilon_1, \varepsilon_2) \subset \mathbb{C}^2 \), for small enough \(|\varepsilon_1| + |\varepsilon_2|\). We are now looking for a local holomorphic map \( \Psi(x, y, \lambda) = \psi_\lambda(x, y) \) which preserves \( H \) and \( F \) and transforms \( \tilde{\omega} \) to \( \omega_\lambda \).

We keep the same notations for all the objects, but now think of them from the complex viewpoint. In particular, the parameter \( t \) for the flows \( \sigma^t \) and \( \sigma^i \) is complex and plays the role of “complex time”.

Similarly, \( t(Q) \), \( \tilde{t}(Q) \) and \( r(Q) \) are complex functions which, by construction, are locally holomorphic.

One of the advantages of the complexified picture is that all the leaves \( L_{\varepsilon_1, \varepsilon_2} \) (both regular and singular) are now connected, each of them intersects the section \( \mathcal{N}_1 \) at exactly one point and, moreover, every regular point \( Q \) (even if it belongs to a singular leaf) can be joint with \( \mathcal{N}_1 \) by a continuous path lying on the leaf. Notice that the regular part of each leaf \( L_{\varepsilon_1, \varepsilon_2} \) can be understood as a complex trajectory of the complex flow \( \sigma^t \) or \( \sigma^i \).

The problem coming with “complexification” is that \( t(Q) \) and \( \tilde{t}(Q) \) are not uniquely defined anymore. Indeed, the complex leaf \( L_{\varepsilon_1, \varepsilon_2} = \{ H = \varepsilon_1, F = \varepsilon_2 \} \) is now a two-dimensional surface with a non-trivial topology. In particular, the first homology group of \( L_{\varepsilon_1, \varepsilon_2} \) is non-trivial and this leads to the fact that \( Q \) can be reached from \( \mathcal{N}_1 \) in many different ways, e.g., \( \sigma^{it}(Q_0) = \sigma^{it}(Q_0) = Q \). So we need to make sure that the choice of \( t_1 \) does not affect the final result of (the complex version of) (21) and (22).

Let us discuss this issue in more detail. Consider one particular leaf \( L_{\varepsilon_1, \varepsilon_2} \) (not necessarily regular). It intersects the section \( \mathcal{N}_1 \) at exactly one point \( Q_0 \). For \( Q \in L_{\varepsilon_1, \varepsilon_2} \), consider a path \( \gamma(s) \) connecting this point with \( Q_0 \) so that \( \gamma(0) = Q_0 \) and \( \gamma(1) = Q \).

Each of the vectors of this path can be written as \( \gamma(s) = \sigma^{s}(Q_0) = \tilde{\sigma}^{i(s)}(Q_0) \) with \( t(s), \tilde{t}(s) : [0, 1] \to \mathbb{C} \) being continuous and \( t(0) = \tilde{t}(0) = 0 \). In this way, we set \( t(Q) = t(1) \) and \( \tilde{t}(Q) = \tilde{t}(1) \). It is easy to see that deforming \( \gamma(s) \) continuously does not change \( t(Q) \) and \( \tilde{t}(Q) \). Thus, \( t(Q) \) and \( \tilde{t}(Q) \) (and consequently \( r(Q) = t(Q) - \tilde{t}(Q) \)) are uniquely defined if we fix the homotopy type of a curve connecting \( Q_0 \) and \( Q \). If we choose two homotopically different curves \( \gamma_1 \) and \( \gamma_2 \), then, in general, \( t_1(Q) \neq t_2(Q) \) and \( \tilde{t}_1(Q) \neq \tilde{t}_2(Q) \).

The condition we need is \( r_1(Q) = t_1(Q) - \tilde{t}_1(Q) = t_2(Q) - \tilde{t}_2(Q) = r_2(Q) \) or, equivalently, \( t_1(Q) - t_2(Q) = \tilde{t}_1(Q) - \tilde{t}_2(Q) \). The latter has a very simple geometric meaning. Indeed, \( Q = \sigma^{t_1(Q)}(Q_0) = \sigma^{t_2(Q)}(Q_0) \) implies that \( \sigma^{t_1(Q)-t_2(Q)}(Q) = Q \). In other words, \( t_1(Q) - t_2(Q) \) is the period of \( L_{\varepsilon_1, \varepsilon_2} \) as a “complex trajectory” of the flow \( \sigma^t \), which corresponds to the (homotopy class of the) loop formed by the curves \( \gamma_1 \) and \( -\gamma_2 \). Hence, the condition \( r_1(Q) = r_2(Q) \) can be formulated as follows: for each loop \( \gamma \) on \( L_{\varepsilon_1, \varepsilon_2} \), the corresponding periods of the Hamiltonian flows generated by \( H_\lambda \) w.r.t. \( \omega_\lambda \) and \( \tilde{\omega}_\lambda \) coincide:

\[ \Pi_\gamma(H, \lambda) = \tilde{\Pi}_\gamma(H, \lambda), \]  

where (compare with (15))
\[ \Pi_\gamma(H, \lambda) = \int_{\gamma} \omega_\lambda \quad \text{and} \quad \tilde{\Pi}_\gamma(H, \lambda) = \int_{\gamma} \tilde{\omega}_\lambda, \]

for any closed loop \( \gamma \) on \( L_{\varepsilon_1, \varepsilon_2} = L_{H, \lambda} \) (equivalently, for any cycle of the first homology group).

Let us assume that this condition holds true (below we will explain why, under our assumptions, this is indeed the case) and make the next step of our construction. As just shown, (23) guarantees that the function \( r(Q) \) is well defined for any point \( Q \) that can be reached by the flows \( \sigma^t \) and \( \sigma^i \) starting from the section \( \mathcal{N}_1 \). Since (after complexification!) every regular point satisfies this property, \( r(Q) \) is defined everywhere except for singular points and is locally holomorphic by construction. But the set of singular points,

\[ \left\{ \frac{\partial H}{\partial x} = 0, \quad \frac{\partial H}{\partial y} = 0 \right\} = \{ x = 0, \ 3y^2 + \lambda = 0 \}, \]

is an algebraic variety of (complex) codimension 2, and therefore by the second Riemann extension theorem ([17, Theorem 4.4] or [16, Theorem 7.2]), \( r(Q) \) can be extended up to a holomorphic function defined
everywhere in the considered domain. In particular, this function is bounded and therefore, by taking a smaller neighborhood of the parabolic point, we may assume that the flow $\sigma'$ is well defined for all $t$ satisfying $|t| \leq \max |r(Q)|$.

After this, our formula (22) can be applied to every point from this neighborhood giving a well defined holomorphic map $\Psi$ with required properties. It remains to return to the real world (i.e., restrict $\psi_\lambda$ to the real part of our complex neighborhood) and we are done.

To complete the proof we need to explain why condition (23) is fulfilled in our case. First we notice that the first homology group of complex leaves $L_{\varepsilon_1,\varepsilon_2}$ is generated by 2 cycles (topologically, $L_{\varepsilon_1,\varepsilon_2}$ is a torus with one hole if $(\varepsilon_1, \varepsilon_2) \notin \Sigma^C = \{(\varepsilon_1^n, -\frac{1}{2^n}\varepsilon_2^n) \mid n \geq 1\}$, a 2-disk with one hole if $(\varepsilon_1, \varepsilon_2) = (0, 0)$, and a pinched torus with one hole otherwise, where one of the basic cycles is pinched to a point).

Consider the (real) “swallow-tail domain” $(\varepsilon_1, \varepsilon_2) \in \mathbb{R}^2 \setminus \{(\varepsilon_1^n, -\frac{1}{2^n}\varepsilon_2^n) \mid n \geq 1\} \subset \{\lambda < 0\}$. Then one of these two cycles can be chosen real. Such a cycle is shown in Fig. 2 as a small loop, whose periods w.r.t. $\omega$ and $\tilde{\omega}_\lambda$ were denoted by $\Pi_\sigma(H, \lambda)$ and $\tilde{\Pi}_\sigma(H, \lambda)$. By our assumption $\Pi_\sigma(H, \lambda) = \tilde{\Pi}_\sigma(H, \lambda)$, i.e., one of the required conditions coincides with the second condition (ii) of Proposition 5.1.

Now consider condition (i) for $(\varepsilon_1, \varepsilon_2) \in \mathbb{R}^2 \setminus \{(\varepsilon_1^n, -\frac{1}{2^n}\varepsilon_2^n) \mid n \geq 1\} \subset \{\lambda < 0\}$. When approaching a hyperbolic singular leaf, the functions $\Pi(H, \lambda)$ and $\tilde{\Pi}(H, \lambda)$ both have logarithmic singularity. This is a well known property of non-degenerate hyperbolic points ([10, 6]), in other words, they have the following asymptotics:

$$\Pi(H, \lambda) = \alpha(H, \lambda) \ln \left|3\sqrt{3}H - 2(-\lambda)^{3/2}\right| + \beta(H, \lambda),$$

$$\tilde{\Pi}(H, \lambda) = \tilde{\alpha}(H, \lambda) \ln \left|3\sqrt{3}H - 2(-\lambda)^{3/2}\right| + \tilde{\beta}(H, \lambda)$$

for some real-analytic functions $\alpha, \beta, \tilde{\alpha}, \tilde{\beta}$ in a neighborhood of $\Sigma_{hyp} = \Sigma \cap \{H > 0\}$. Condition (i) of Proposition 5.1, therefore, implies that $\alpha(H, \lambda) = \tilde{\alpha}(H, \lambda)$. For hyperbolic points, this coefficient in front of logarithm is known to be proportional to the period of the second (invisible in the real setting) cycle on the complex leaf $L_{H, \lambda}$ (see e.g. [4] for details).

Thus, for real $\lambda < 0$ and real $H \in (-2(-\lambda)^{3/2}/(3\sqrt{3}), 2(-\lambda)^{3/2}/(3\sqrt{3}))$ the required conditions (23) are fulfilled. Since the periods $\Pi_\sigma$ and $\tilde{\Pi}_\sigma$ are locally holomorphic (we cannot consider them as single-valued functions because of the monodromy phenomenon) and coincide on an open real domain, we conclude that (23) is fulfilled identically, which completes the proof of Proposition 5.1.

We now return to our discussion on symplectic invariants of parabolic trajectories that we started in Section 3. According to Proposition 3.1, this problem can be reduced to the situation explained in Remark 3.2.

Namely, we consider two functions $H = x^2 + y^3 + \lambda y$ and $F = y$ that commute simultaneously with respect to two symplectic forms $\Omega$ and $\tilde{\Omega}$ defined by (11) and (12) with $\omega_\lambda = f(x, y, \lambda)dx \wedge dy$ and $\tilde{\omega}_\lambda = \tilde{f}(x, y, \lambda)dx \wedge dy$ and $f, \tilde{f} > 0$. Combining Proposition 3.3 and Proposition 5.1, we obtain the following

**Proposition 5.2.** The following two statements are equivalent.

1. In a tubular neighborhood of the parabolic orbit $\gamma_0(t) = (0, 0, 0, \varphi = t)$ there is a (real-analytic) diffeomorphism $\Phi$ such that
   - (i) $\Phi$ preserves $H$ and $F$;
   - (ii) $\Phi^* = \Omega$.

2. The functions $\Pi, \Pi_\sigma, \tilde{\Pi}, \tilde{\Pi}_\sigma$ (real-analytic in the complement of the bifurcation diagram) satisfy the relations
   - $\Pi(H, \lambda) = \tilde{\Pi}(H, \lambda)$ is real-analytic (in a neighborhood of the point $H = 0, \lambda = 0$),
   - $\Pi_\sigma(H, \lambda) = \tilde{\Pi}_\sigma(H, \lambda)$.

In fact, the functions $\Pi(H, \lambda)$ and $\Pi_\sigma(H, \lambda)$ are not independent. Indeed, as $H \rightarrow 2(-\lambda)^{3/2}/(3\sqrt{3})$ (i.e., when the real disconnected regular fiber approaches the hyperbolic singular one) these two functions have a logarithmic singularity with the same logarithmic coefficient, that is, we have the following asymptotics:

$$\Pi(H, \lambda) = \alpha(H, \lambda) \ln \left|3\sqrt{3}H - 2(-\lambda)^{3/2}\right| + \beta(H, \lambda),$$

$$\Pi_\sigma(H, \lambda) = \alpha(H, \lambda) \ln \left|3\sqrt{3}H - 2(-\lambda)^{3/2}\right| + \beta_\sigma(H, \lambda).$$

\[2\text{In the domain } \{(\varepsilon_1, \varepsilon_2) \in \mathbb{R}^2 \mid \varepsilon_1^2 > -\frac{1}{2^n}\varepsilon_2^n \}, \text{ similar asymptotics for } \Pi(H, \lambda) \text{ and } \tilde{\Pi}(H, \lambda) \text{ hold, where the coefficients } \alpha, \beta, \tilde{\alpha}, \tilde{\beta} \text{ are replaced by } 2\alpha, \delta, 2\tilde{\alpha}, \delta \text{ for some real-analytic functions } \delta, \tilde{\delta} \text{ in a neighbourhood of } \Sigma_{hyp}.\]
In other words, the functions $\beta(H,\lambda)$ and $\beta_0(H,\lambda)$ are different and not related to each other in any sense, but the coefficients $\alpha(H,\lambda)$ are the same for both functions. According to Proposition 5.2, however, the regular part $\beta(H,\lambda)$ of $\Pi(H,\lambda)$ does not play any role, so that the only important information for us is the coefficient $\alpha(H,\lambda)$ which, as we have just explained, can be "obtained" from $\Pi_0(H,\lambda)$. Hence we conclude that $\Pi_0(H,\lambda)$ contains all the information we need for symplectic characterisation of a parabolic trajectory.

We also note that the period $\Pi_0(H,\lambda)$ of closed trajectories can naturally be interpreted in terms of the action variables of our integrable system. Indeed, the family of small closed trajectories shown on Fig. 2 corresponds to a family of “narrow” two-dimensional Liouville tori (recall that a four-dimensional neighborhood $U(\gamma_0)$ of the parabolic orbit $\gamma_0$ is the product (Fig. 2) $\times S^1$). For this family, we can naturally define two action variables $I_1$ and $I_2$. The first of them corresponds to the free Hamiltonian $S^1$-action on $U(\gamma_0)$ generated by $F = \lambda$, that is, $I_1 = \lambda$. The other $I_2(H,\lambda)$ corresponds to the family of vanishing cycles shown in Fig. 2 as small closed trajectories. We re-denote this function as $I_2(H,\lambda) = I_2(\Pi(H,\lambda),\lambda)$. Without loss of generality we assume that

\begin{equation}
I_2 > 0 \quad \text{and} \quad I_0 \to 0 \quad \text{as} \quad (H,\lambda) \to (H(\gamma_0), F(\gamma_0)),
\end{equation}

i.e., as we approach the singular fiber. Notice that, in a coordinate system $(x, y, \lambda, \varphi)$, $I_0(H,\lambda)$ can be defined by an explicit formula. Fixing $H$ and $\lambda$, we define a unique closed cycle (see Fig. 2). This cycle bounds a certain domain $V_{H,\lambda} \subset \mathbb{R}^2(x,y)$ on the corresponding layer $\{\lambda = \text{const}\}$. Then

\[ I_0(H,\lambda) = \frac{1}{2\pi} \text{area}_c(V_{H,\lambda}) = \frac{1}{2\pi} \int_{V_{H,\lambda}} \omega_\lambda. \]

It is well-known that $I_0(H,\lambda)$ and $\Pi_0(H,\lambda) > 0$ are related in the following very simple way:

\[ \Pi_0(H,\lambda) = 2\pi \frac{\partial}{\partial H} I_0(H,\lambda), \]

which shows that $\Pi_0(H,\lambda)$ can be reconstructed from $I_0(H,\lambda)$, so that we finally come to the following equivalent version of Proposition 5.2.

**Proposition 5.3.** Under the assumptions of Proposition 5.2, the following two statements are equivalent.

(i) In a tubular neighborhood of the parabolic orbit $\gamma_0$ there is a (real-analytic) diffeomorphism $\Phi$ such that

- $\Phi$ preserves $H$ and $F$;
- $\Phi^* (\Omega) = \Omega$.

(ii) The actions (real-analytic on the “swallow-tail domain” corresponding to a family of “narrow” Liouville tori) corresponding to the family of vanishing cycles (cf. (24)) coincide, $I_0(H, F) = I_0(H, F)$.

We now want to give one more version of the criterion for the existence of $\Phi$ by omitting the condition $F = \lambda$ which, in particular, means that $F$ is a $2\pi$-periodic integral (equivalently, the action variable $I_1$) simultaneously for both integrable systems.

Consider $H$ and $F$ commuting with respect to $\Omega$ and $\tilde{\Omega}$ in a tubular neighborhood of a parabolic orbit $\gamma_0$. Notice that now we are not allowed to assume that these two integrable systems share the same canonical coordinate system $(x, y, \lambda, \varphi)$ as we did in Propositions 5.2 and 5.3.

Let $dF|_{\gamma_0} \neq 0$. We say that $\Omega$ and $\tilde{\Omega}$ induce

- the same orientation if the Hamiltonian flows of $F$ w.r.t. $\Omega$ and $\tilde{\Omega}$ induce the same orientation of $\gamma_0$;
- the same coorientation if (the restrictions of) $\Omega$ and $\tilde{\Omega}$ induce the same orientation of a (local) 2-dimensional surface in $\{F = F(\gamma_0)\}$ transversal to $\gamma_0$ (i.e., on a 2-dim Poincaré section).

Without loss of generality, we assume that $\Omega$ and $\tilde{\Omega}$ induce the same orientation and the same coorientation of $\gamma_0$. Indeed, we can easily achieve this condition by using additional maps $(x, y, \lambda, \varphi) \mapsto (x, y, \lambda, -\varphi)$ and $(x, y, \lambda, \varphi) \mapsto (-x, y, \lambda, \varphi)$ (written in a canonical coordinate system from Proposition 3.1) that change respectively the orientation and coorientation without changing the functions $F$ and $H$.

As above we can define two natural action variables for each of these two integrable systems $I(H, F)$, $I_0(H, F)$ and $\tilde{I}(H, F)$, $\tilde{I}_0(H, F)$. Here $I(H, F)$ and $\tilde{I}(H, F)$ are smooth on a certain neighborhood $U(\gamma_0)$ and are generators of the Hamiltonian $S^1$-actions w.r.t. $\Omega$ and $\tilde{\Omega}$ respectively.

Alternatively, we may define $I(H, F)$ by

\begin{equation}
I(H, F) = \frac{1}{2\pi} \oint_{\gamma} x, \quad \text{where} \quad dx = \Omega
\end{equation}
and \( \gamma = \gamma_{H,F} \) is a closed cycle on the fiber \( E_{H,F} \) that is homotopic to \( \gamma_0 \) (recall that locally our fibration can be understood as the direct product of \( S^1 \) and a three-dimensional foliated domain \( V \) shown in Figure 2, then \( \gamma_{H,F} \) can be taken of the form \( S^1 \times \{ P \} \) where \( P \in V \) is a point lying on the corresponding fiber).

The other action variable \( I_\circ(H,F) \) is only defined on the family of “narrow” Liouville tori corresponding to small oriented loops \( \mu_\circ = \mu_\circ(H,F) \) shown in Fig. 2:

\[
I_\circ(H,F) = \frac{1}{2\pi} \oint_{\mu_\circ} \kappa, \quad \text{where} \ d\kappa = \Omega.
\]

In other words, \( I_\circ(H,F) \) is a function defined on the “swallow-tail” domain on \( \mathbb{R}^2(H,F) \) bounded by the bifurcation diagram \( \Sigma \) (this definition coincides with (24) up to, perhaps, changing the sign).

The actions \( \hat{I}(H,F) \) and \( \hat{I}_\circ(H,F) \) for the second system are defined in a similar way by integrating \( \tilde{\kappa} \), \( d\tilde{\kappa} = \tilde{\Omega} \), over the same cycles \( \gamma \) and \( \mu_\circ \) with the same orientations.

**Theorem 5.4.** Suppose that the singular fibration defined by the functions \( H \) and \( F \) is Lagrangian w.r.t. both the symplectic forms \( \Omega \) and \( \tilde{\Omega} \). Suppose that \( \Omega \) and \( \tilde{\Omega} \) induce the same orientation and the same coorientation of a parabolic orbit \( \gamma_0 \). Then the following two statements are equivalent.

(i) In a tubular neighborhood of the parabolic orbit \( \gamma_0 \) there is a (real-analytic) diffeomorphism \( \Phi \) such that

- \( \Phi \) preserves \( H \) and \( F \);
- \( \Phi^*(\tilde{\Omega}) = \Omega \).

(ii) These two integrable systems have common action variables described above, i.e.,

\[
I(H,F) = \hat{I}(H,F) + \text{const} \quad \text{and} \quad I_\circ(H,F) = \hat{I}_\circ(H,F).
\]

**Proof.** Suppose (ii) holds true. First of all we replace the functions \( F \) and \( H \) by new functions \( \hat{F} \) and \( \hat{H} \) satisfying the following conditions (cf. Proposition 2.1 and Remark 2.2):

- \( \hat{F} = \pm I(H,F) + \text{const} \) where \( \pm \) and \( \text{const} \) are chosen in such a way that \( \hat{F} = 0 \) on the parabolic trajectory \( \gamma_0 \) and \( \tilde{F} < 0 \) on the swallow-tail domain of the bifurcation diagram;
- \( \hat{H} \) is chosen in such a way that the bifurcation diagram of \( \hat{F} = (\hat{F}, \hat{H}) \) takes the standard form (9).

After this we apply Proposition 3.2 which says that formulas from Proposition 3.1 holds true exactly for the functions \( \hat{F} \) and \( \hat{H} \). In other words, we can introduce two different “good” coordinate systems \( (x,y,\lambda,\varphi) \) and \( (\tilde{x},\tilde{y},\tilde{\lambda},\tilde{\varphi}) \) as in Proposition 3.1 for \( (\hat{H},\hat{F},\Omega) \) and \( (\hat{H},\hat{F},\tilde{\Omega}) \) respectively (notice that \( \lambda = \tilde{\lambda} \) automatically as both \( \lambda \) and \( \tilde{\lambda} \) coincide with \( \hat{F} \)).

The next step is to consider the map \( \Psi : (x,y,\lambda,\varphi) \mapsto (\tilde{x},\tilde{y},\tilde{\lambda},\tilde{\varphi}) \) and after this continue working with the forms \( \Omega \) and \( \Psi^*(\tilde{\Omega}) \). Now \((x,y,\lambda,\varphi)\) is a common “good” coordinate system for both systems and the conditions of Theorem 5.4 are still fulfilled for \( \Omega \) and \( \Psi^*(\tilde{\Omega}) \). After this, it remains to apply Proposition 5.3 for the integrable systems \((\hat{H},\hat{F},\Omega)\) and \((\hat{H},\hat{F},\Psi^*(\tilde{\Omega}))\).

The fact that (i) implies (ii) follows from the assumption that the symplectic forms \( \Omega \) and \( \tilde{\Omega} \) induce the same orientation and coorientation on \( \gamma_0 \). Indeed this implies that \( \Phi \) preserves the homology class of \( \gamma \) and \( \mu_\circ \) on each “narrow” torus. Therefore if we set \( \kappa = \Phi^* \tilde{\kappa} \) in the definition of the actions \( I(H,F) \) and \( I_\circ(H,F) \), then \( I(H,F) = \hat{I}(H,F) \) and \( I_\circ(H,F) = \hat{I}_\circ(H,F) \). \( \Box \)

Notice that due to analyticity it is sufficient to compare the actions only on the family of “narrow” tori, although \( I \) and \( \hat{I} \) are defined on the whole neighborhood \( U(\gamma_0) \).

**Remark 5.1.** In fact, we do not even need to mention \( H \) and \( F \) in the statement of Theorem 5.4 at all and can equivalently reformulate it as follows:

Consider a singular fibration with a parabolic orbit \( \gamma_0 \) which is Lagrangian with respect to two symplectic structures \( \Omega \) and \( \tilde{\Omega} \). Suppose that \( \Omega \) and \( \tilde{\Omega} \) induce the same orientation and the same coorientation of \( \gamma_0 \). The necessary and sufficient condition for the existence of a (real-analytic) diffeomorphism \( \Phi \) in a tubular neighborhood of \( \gamma_0 \) sending each fiber to itself and such that \( \Phi^*(\tilde{\Omega}) = \Omega \) is that these two systems have common action variables in the sense that for every closed cycle \( \tau \) on any “narrow” torus we have

\[
\oint_{\tau} \kappa = \oint_{\tau} \tilde{\kappa}, \quad \text{for} \ d\kappa = \Omega, \ d\tilde{\kappa} = \tilde{\Omega},
\]

where \( \kappa \) and \( \tilde{\kappa} \) are chosen in such a way that \( \oint_{\gamma_0} \kappa = \oint_{\gamma_0} \tilde{\kappa} = 0 \).
Finally, we want to relax the condition that each fiber goes to itself (indeed, this assumption makes no sense at all if we want to compare parabolic orbits for two different integrable systems).

Assume that we are given two integrable systems with parabolic orbits $\gamma_0$ and $\tilde{\gamma}_0$, respectively. For both systems we consider the bifurcation diagrams (or bifurcation complexes), $\Sigma$ and $\tilde{\Sigma}$ respectively, and the “swallow-tail domains” corresponding to the families of “narrow” Liouville tori. On each of these domains we have two actions $I$ and $I_0$ (as functions of $H$ and $F$) and correspondingly $\tilde{I}$ and $\tilde{I}_0$ (as functions of $\tilde{H}$ and $\tilde{F}$) defined as above. Without loss of generality we assume that these action variables are “normalised” in such a way that

- all of them vanish at the corresponding cusp point,
- $I_0$ and $\tilde{I}_0$ are positive on the corresponding “swallow-tail” domains,
- $I$ and $\tilde{I}$ are negative on the corresponding “swallow-tail” domains.

Combining Theorem 5.4 with Proposition 2.3 we obtain

**Theorem 5.5.** Given two integrable systems $H, F$ and $\tilde{H}, \tilde{F}$ containing parabolic orbits $\gamma_0$ and $\tilde{\gamma}_0$, there exists a real analytic fiberwise symplectomorphism $\Phi : U(\gamma_0) \to \tilde{U}(\tilde{\gamma}_0)$ between some tubular neighborhoods $U(\gamma_0)$ and $\tilde{U}(\tilde{\gamma}_0)$ if and only if there is a real-analytic diffeomorphism

$$
\phi : (H, F) \mapsto (\tilde{H}, \tilde{F})
$$

between some neighborhoods of the cusp points $(H(\gamma_0), F(\gamma_0))$ and $(\tilde{H}(\tilde{\gamma}_0), \tilde{F}(\tilde{\gamma}_0))$ in $\mathbb{R}^2$ which

- respects the bifurcation diagrams together with their partitions into hyperbolic and elliptic branches$^3$:
  $$\phi(\Sigma) = \tilde{\Sigma}, \text{ moreover } \phi(\Sigma_{\text{ell}}) = \tilde{\Sigma}_{\text{ell}} \text{ and } \phi(\Sigma_{\text{hyp}}) = \tilde{\Sigma}_{\text{hyp}},$$
- preserves the action variables on the “swallow-tail domains”, i.e., $I = \tilde{I} \circ \phi$ and $I_0 = \tilde{I}_0 \circ \phi$ or, in more detail:
  $$I(H, F) = \tilde{I}(\tilde{H}(H, F), \tilde{F}(H, F)) \quad \text{and} \quad I_0(H, F) = \tilde{I}_0(\tilde{H}(H, F), \tilde{F}(H, F)),$$

where $I, I_0, \tilde{I}, \tilde{I}_0$ are defined in (25) and (26).

The latter conclusion basically means that the only symplectic invariants of parabolic orbits are action variables. This conclusion does not provide any tools to decide whether a suitable map (27) (making the actions equal) exists or not, but some necessary conditions can be easily found. Some of them have been already described in Section 4, e.g., the function $f(\cdot)$ from Proposition 4.11. This function is a symplectic invariant of a parabolic singularity which “corresponds” to the level $\lambda = 0$, where $\lambda$, as above, denotes the first action variable $I(H, F)$. We now want to describe another non-trivial symplectic invariant which is a function $h(\lambda)$, $\lambda < 0$.

Since $\lambda = \lambda(H, F)$ is a real-analytic function, we can consider it as a parameter on the hyperbolic branch $\Sigma_{\text{hyp}}$ of the bifurcation diagram $\Sigma$. Consider $I_0(H, \lambda)$ as a function of $H$ (with $\lambda$ as a parameter). This function is defined on the interval

$$
\left(-2(-\lambda)^{3/2}/(3\sqrt{3}), 2(-\lambda)^{3/2}/(3\sqrt{3})\right),
$$

is strictly increasing from 0 to its maximum attained on the hyperbolic branch. We denote it by $h(\lambda) = \max_H I_0(H, \lambda)$. Obviously, $h(\lambda)$ does not depend on the choice of commuting functions $H$ and $F$ defining the Lagrangian fibration, so that $h(\lambda)$ can be considered as a symplectic invariant of a parabolic singularity.

The problem of an explicit description of a complete set of symplectic invariants is equivalent, as shown above, to the analysis of the asymptotics of the function $I_0(H, \lambda)$. More precisely, we should describe invariants of such functions under (real-analytic) transformations of the form $(H, \lambda) \mapsto (\tilde{H}(H, \lambda), \tilde{\lambda} = \lambda)$.

6. Semi-local symplectic invariants of cusp singularities

Finally, we want to describe semi-local invariants of cusp singularities. In other words, we now consider a saturated neighborhood of a compact singular fiber $\mathcal{L}_0$ containing a parabolic orbit, i.e., cuspidal torus. We assume that this fiber contains no other critical points, so that the topology of the fibration in a neighborhood of $\mathcal{L}_0$ is standard and illustrated in Figure 3. This Figure also shows the bifurcation complex, i.e., the base of this fibration, which consists of two 2-dimensional strata (attached to each other along $\Sigma_{\text{hyp}}$, one of the branches of the bifurcation diagram $\Sigma$ that corresponds to the family of hyperbolic orbits). Each stratum represents a family of Liouville tori and therefore we can naturally assign a pair of action variables to each of them. Our goal is to show that fibrations with the same actions are symplectomorphic.

---

$^3$Equivalently, we may say that $\phi$ defines a (local) homeomorphism between the corresponding bifurcation complexes.
In a neighborhood $U(\mathcal{L}_0)$ of the singular fiber $\mathcal{L}_0$, on all neighboring Liouville tori we can choose a natural basis of cycles in the first homology group of $H_1(T^2_{F,H},\mathbb{Z})$ where $T^2_{F,H}$ is the Liouville torus defined by fixing the values of the integrals $F$ and $H$ respectively. These cycles are shown in Figure 3. One of them corresponds to the $S^1$-action defined on $U(\mathcal{L}_0)$ (in Figure 3, this cycle $\gamma$ is denoted by $S^1$).

The other cycle can be obtained by considering a global 3-dimensional cross-section to this $S^1$-action. Since this $S^1$-action (and the corresponding $S^1$-fibration) is topologically trivial, such a cross section exists. It is illustrated on the left in Figure 3 and denoted by $V$ so that we may think of $U(\mathcal{L}_0)$ as the direct product $V \times S^1 = U(\mathcal{L}_0)$. Each Liouville torus $T^2_{F,H}$ intersects $V$ along a closed curve (these curves are shown in Figure 3) and this curve is taken as the second basis cycle in $\mathbb{Z}$ more precisely, we need to take into account that for a point $(F,H)$ from the swallow-tail zone, we have two disjoint Liouville tori. The corresponding cycles will be denoted by $\mu$ and $\mu_0$, where $\mu_0$ is used for the vanishing cycle on the family of “narrow” tori, the other, i.e., $\mu$, corresponds to a “wide” torus.

Notice that the first cycle $\gamma$ is uniquely defined by the $S^1$-action. The cycle $\mu_0$ is also well defined by the topology of the fibration (as a vanishing cycle). The other cycle $\mu$ is not. It is easy to see that $\mu$ is defined up to the transformation of the form $\mu \mapsto \mu + k\gamma$, $k \in \mathbb{Z}$. This is caused by ambiguity in the choice of the cross-section $V$ which can be chosen in many homotopically different ways (this phenomenon is discussed and explained in details in [3]).

Summarizing, on each stratum of the bifurcation complex, we have a pair of action variables $I_\gamma$, $I_\mu$ and $I_\gamma$, $I_{\mu_0}$ (the latter for the swallow-tail stratum). Each of these functions can be treated as a real-analytic function of $H$ and $F$. In fact, we have already considered the actions $I_\gamma$, $I_{\mu_0}$ in the previous Section 5, where they were denoted by $I(H,F)$ and $I_{\mu_0}(H,F)$. We keep this notation here, i.e., we set $I_\gamma = I$, $I_{\mu_0} = I_0$. The remaining action is denoted by $I_\mu$ so that we have 3 action variables $I$, $I_0$ and $I_\mu$. The first two of them are well-defined, but $I_\mu$ is defined modulo transformation $I_\mu \mapsto I_\mu + kI$.

Also notice that $I(H,F)$ is real-analytic everywhere (strictly speaking we need to distinguish this action for the families of “narrow” and “wide” tori, but due to real-analyticity $I(H,F)$, as function of $H$ and $F$, is the same for both families). The function $I_{\mu_0}(H,F)$ is defined and is real-analytic everywhere except for the hyperbolic branch $\Sigma_{\text{hyp}}$ of the bifurcation diagram. When approaching $\Sigma_{\text{hyp}}$ the function tends to certain finite limits, but these limits from above and from below are different. The function $I_0$ is defined on the swallow-tail domain and is continuous on its closure.

Our final result basically says that the systems with equal actions are symplectomorphic. Consider two integrable Hamiltonian systems $(H,F,\Omega,U(\mathcal{L}_0))$ and $(\tilde{H},\tilde{F},\tilde{\Omega},\tilde{U}(\mathcal{L}_0))$ defined on some neighborhoods of cuspidal tori $\mathcal{L}_0$ and $\tilde{\mathcal{L}}_0$. For each system, introduce the actions $I(H,F)$, $I_0(H,F)$ and $I_{\mu}(H,F)$ and $I_{\mu_0}(H,F)$ respectively $I(H,F)$, $I_0(H,F)$ and $I_{\mu_0}(H,F)$ as explained above.

**Theorem 6.1.** Assume that there is a local real-analytic diffeomorphism $\phi : (H,F) \mapsto (\tilde{H},\tilde{F})$, $\tilde{H} = \tilde{H}(H,F)$ and $\tilde{F} = \tilde{F}(H,F)$ that

- respects the bifurcation diagrams together with their partitions into hyperbolic and elliptic branches:
  $\phi(\Sigma) = \tilde{\Sigma}$, moreover $\phi(\Sigma_{\text{ell}}) = \tilde{\Sigma}_{\text{ell}}$ and $\phi(\Sigma_{\text{hyp}}) = \tilde{\Sigma}_{\text{hyp}}$.

- makes the actions equal (for some choice of $\mu$ and $\mu_0$):
  $I = I \circ \phi$, $I_0 = I_0 \circ \phi$ and $I_{\mu} = I_{\tilde{\mu}} \circ \phi$.

Then there exists a fiberwise symplectomorphism $\Phi : U(\mathcal{L}_0) \rightarrow \tilde{U}(\mathcal{L}_0)$.

**Remark 6.1.** Notice that the converse statement is also true: a fiberwise symplectomorphism $\Phi : U(\mathcal{L}_0) \rightarrow \tilde{U}(\mathcal{L}_0)$ induces a diffeomorphism $\phi$ between the bases of the fibrations which automatically satisfies the properties above (where the choice of $\mu_0$ is induced by $\Phi$ and $\mu$).

**Remark 6.2.** We can rewrite this statement in a slightly different and shorter way. For each of the above integrable systems, consider the momentum map $\pi : U(\mathcal{L}_0) \rightarrow B \subset \mathbb{R}^2(H,F)$ and $\tilde{\pi} : \tilde{U}(\mathcal{L}_0) \rightarrow \tilde{B} \subset \mathbb{R}^2(\tilde{H},\tilde{F})$, where $B$ and $\tilde{B}$ are some neighborhoods of the corresponding cusp points of the bifurcation diagrams. We can think of the actions as functions on $B$ (more precisely on the corresponding domains defined by the bifurcation diagrams). Then Theorem 6.1 can be rephrased as follows:

Assume that there exists a local real-analytic diffeomorphism $\phi : B \rightarrow \tilde{B}$ respecting the bifurcation diagrams $\Sigma$ and $\tilde{\Sigma}$ and such that $I = I \circ \phi$, $I_0 = I_0 \circ \phi$ and $I_{\mu} = I_{\tilde{\mu}} \circ \phi$. Then there exist a fiberwise symplectomorphism $\Phi : U(\mathcal{L}_0) \rightarrow \tilde{U}(\mathcal{L}_0)$.

---

4We do not specify the sizes of these neighborhoods, but assume that they are sufficiently small. In other words, we are talking about germs of fibrations and germs of maps.
Another, slightly weaker but useful, version of Theorem 6.1 is as follows. Let \( \Psi : U(L_0) \to \tilde{U}(\tilde{L}_0) \) be a fiberwise diffeomorphism that preserves the actions in the sense that

\[
\oint_{\Psi(\tau)} \tilde{\kappa} = \oint_{\tau} \kappa
\]

for every cycle \( \tau \subset L_0 \) and some 1-forms \( \kappa \) and \( \tilde{\kappa} \) satisfying \( d\kappa = \Omega \), \( d\tilde{\kappa} = \tilde{\Omega} \). Then there exists a fiberwise symplectomorphism \( \Phi : U(L_0) \to \tilde{U}(\tilde{L}_0) \).

The proof of Theorem 6.1 is based on the following lemma. Consider two (non-singular) integrable systems \( (H, F, \Omega) \) and \( (\tilde{H}, \tilde{F}, \tilde{\Omega}) \) defined in some neighborhoods \( T^2 \times B \) and \( \tilde{T}^2 \times \tilde{B} \) of regular Liouville tori. Here \( B \) and \( \tilde{B} \) are 2-dimensional discs viewed as the bases of the corresponding (regular) Lagrangian fibrations endowed with induced integer affine structures (action variables). The functions \( (H, F) \) and \( (\tilde{H}, \tilde{F}) \) are treated as smooth functions on \( B \) and \( \tilde{B} \) respectively. We also consider the Hamiltonian \( \mathbb{R}^2 \)-actions \( \sigma(t_1, t_2) \) and \( \tilde{\sigma}(t_1, t_2) \), \( (t_1, t_2) \in \mathbb{R}^2 \) generated by the commuting functions \( (H, F) \) and \( (\tilde{H}, \tilde{F}) \). Here \( \sigma(t_1, t_2) \) denotes the composition of the Hamiltonian shifts along vector fields \( X_H \) and \( X_F \) by time \( t_1 \) and\( \tilde{t}_2 \) respectively. Similarly for \( \tilde{\sigma}(t_1, t_2) \).

**Lemma 6.2.** Let \( \phi : B \to \tilde{B} \) be a real-analytic diffeomorphism which provides an (integer) affine equivalence between \( B \) and \( \tilde{B} \). Set \( \tilde{H} = \tilde{H} \circ \phi \) and \( \tilde{F} = \tilde{F} \circ \phi \) and consider two Liouville tori \( T_p = T^2 \times \{p\} \) and \( \tilde{T}_p = \tilde{T}^2 \times \{\phi(p)\} \) where \( p \in B \) (in other words, these tori correspond to each other under the map \( \phi : B \to \tilde{B} \)). Let \( x \in T_p \) and \( \tilde{x} \in \tilde{T}_p \) be arbitrary two points from these fibers.

Then \( \sigma(t_1, t_2)(x) = x \) (or more generally \( \sigma(t_1, t_2)(x) = \sigma(t_1, t_2)(x) \)) if and only if \( \tilde{\sigma}(t_1, t_2)(\tilde{x}) = \tilde{x} \) (respectively \( \tilde{\sigma}(t_1, t_2)(\tilde{x}) = \tilde{\sigma}(t_1, t_2)(\tilde{x}) \)).

**Proof.** We will give a proof of this statement in the case of \( n \) degrees of freedom. Recall that \( B \) and \( \tilde{B} \) are endowed with integer affine structures induced by the action variables. By definition, \( \phi : B \to \tilde{B} \) is an (integer) affine equivalence if \( \phi \) sends “actions to actions”. More precisely, let \( \tilde{I}_1, \ldots, \tilde{I}_n \) be action variables for \( \tilde{B} \), which means that these functions define the Hamiltonian action of the standard torus \( \mathbb{R}^n / \Gamma_0 \) where...
\( \Gamma_0 = \mathbb{Z}^n \) is the standard integer lattice in \( \mathbb{R}^n \). We say that \( \phi : B \to \tilde{B} \) is an affine equivalence, if \( I_1 = \tilde{I}_1 \circ \phi, \ldots, I_n = \tilde{I}_n \circ \phi \) are action variables on \( B \).

If in Lemma 6.2 instead of \((H,F)\) and \((\tilde{H},\tilde{F})\) we consider \((I_1,I_2)\) and \((\tilde{I}_1,\tilde{I}_2)\), then the statement is obvious: both relations \( \sigma^{(t_1,t_2)}(x) = x \) and \( \tilde{\sigma}^{(\tilde{t}_1,\tilde{t}_2)}(\tilde{x}) = \tilde{x} \) simply mean that \((t_1,t_2)\) belongs to the standard integer lattice, i.e., \( t_1, t_2 \in \mathbb{Z} \).

Let us see what happens if we take arbitrary functions \((H,F)\) or, more generally, \((F_1,F_2,\ldots,F_n)\) in the case of \( n \) degrees of freedom. The relation \( \sigma^{(t_1,\ldots,t_n)}(x) = x \) means that \((t_1,\ldots,t_n)\) belongs to the period lattice \( \Gamma \subset \mathbb{R}^n \) which is the stationary subgroup of \( x \) in the sense of the Hamiltonian \( \mathbb{R}^n \)-action generated by \( F_1,F_2,\ldots,F_n \). Since this lattice is the same for any point \( x \) from a fixed torus \( T_p, p \in B \), we may denote it by \( \Gamma(T_p) \). This lattice is not standard anymore and it depends on two things, the torus \( T_p \) (or just a point \( p \in B \)) and the generators \( F_1,F_2,\ldots,F_n \) of the Hamiltonian \( \mathbb{R}^n \)-action.

If we know the expressions of \( F_1,\ldots,F_n \) in terms of the actions \( I_1,\ldots,I_n \), then the lattice \( \Gamma(T_p) \) is easy to describe. Namely:
\[
\Gamma(T_p) = \Gamma_0 \cdot \cdot J^{-1}(p),
\]
where \( \Gamma_0 \) is the standard integer lattice and \( J(p) \) denotes the Jacobi matrix \( J(p) = \left( J_j = \frac{\partial F_i}{\partial t_j} \right) \).

In more details,
\[
(t_1,\ldots,t_n) \in \Gamma(T_p) \quad \text{if and only if} \quad (t_1,\ldots,t_n) = (k_1,\ldots,k_n) \cdot J^{-1}(p)
\]
for \((k_1,\ldots,k_n) \in \Gamma_0\), i.e., for some vector with integer components \(k_i \in \mathbb{Z}\).

The same, of course, holds for \( \tilde{x} \in \tilde{T}_{\phi(p)} \), that is
\[
(t_1,\ldots,t_n) \in \Gamma(\tilde{T}_{\phi(p)}) \quad \text{if and only if} \quad (t_1,\ldots,t_n) = (k_1,\ldots,k_n) \cdot \tilde{J}^{-1}(\phi(p))
\]
where \( \tilde{J}(\phi(p)) = \left( \tilde{J}_j = \frac{\partial \tilde{F}_i}{\partial \tilde{t}_j} \right) \).

It remains to notice that under our assumptions these matrices coincide.

The reason is obvious: since \( I_1 = \tilde{I}_1 \circ \phi \) and also \( \tilde{F}_i = \tilde{F}_i \circ \phi \), we see that \( F_i = f_i(I_1,\ldots,I_n) \) implies that \( \tilde{F}_i = \tilde{f}_i(\tilde{I}_1,\ldots,\tilde{I}_n) \), i.e., \( F_i \) depends on \( I_1,\ldots,I_n \) exactly in the same way as \( \tilde{F}_i \) depends on \( \tilde{I}_1,\ldots,\tilde{I}_n \) so that the corresponding partial derivatives (being computed at \( p \) and \( \phi(p) \), i.e., at those points for which \((I_1,\ldots,I_n) = (\tilde{I}_1,\ldots,\tilde{I}_n)\)) obviously coincide. In other words, we have proved that \( \Gamma(T_p) = \Gamma(\tilde{T}_{\phi(p)}) \), which is equivalent to our statement. \( \square \)

This lemma implies the following two extension results.

Under the assumptions and notation from Lemma 6.2, assume that \( N \) and \( \tilde{N} \) are Lagrangian (real-analytic) sections of the Lagrangian fibrations \( \pi : T^2 \times B \to B \) and \( \tilde{\pi} : \tilde{T}^2 \times \tilde{B} \to \tilde{B} \) respectively. Since the sections \( N \) and \( \tilde{N} \) can be naturally identified with the bases \( B \) and \( \tilde{B} \), the map \( \phi : B \to \tilde{B} \) induces a natural map between \( N \) and \( \tilde{N} \) which we denote by the same letter \( \phi : N \to \tilde{N} \). For any point \( y \in T^2 \times B \) we can find (not uniquely!) \( (t_1(y),t_2(y)) \in \mathbb{R}^2 \) such that \( x = \sigma^{(t_1(y),t_2(y))}(y) \in N \). Consider the map \( \Phi : T^2 \times B \to \tilde{T}^2 \times \tilde{B} \) defined by
\[
\Phi(y) = \tilde{\sigma}^{(-t_1(y),-t_2(y))}(\phi(x)), \quad \text{where} \quad x = \sigma^{(t_1(y),t_2(y))}(y) \in N.
\]

**Corollary 6.3.** The map \( \Phi(y) \) is well defined and is a fiber-wise real-analytic diffeomorphism satisfying \( \Phi^*(\tilde{\Omega}) = \Omega \).

**Proof.** The fact that \( \Phi \) is well defined (i.e., does not depend on the choice of \((t_1,t_2)\in \mathbb{R}^2 \) with the property \( \sigma^{(t_1,t_2)}(y) \in N \)) follows from Lemma 6.2. To show that \( \Phi \) is symplectomorphism, i.e., \( \Phi^*(\tilde{\Omega}) = \Omega \), we notice that the position of each point \( y \in T^2 \times B \) is defined by the values of \( H,F \) (which can be understood as coordinates on \( B \)) and \( t_1,t_2 \) (which can be understood as coordinates on the torus \( T^2 \) with the "origin" \((0,0)\) located on \( N \)). These four functions define a canonical coordinate system, i.e.,
\[
\Omega = dH \wedge dt_1 + dF \wedge dt_2.
\]
A similar canonical coordinate system \( \tilde{H}, \tilde{F}, \tilde{t}_1, \tilde{t}_2 \) can be defined on \( \tilde{T}^2 \times \tilde{B} \) by using the action \( \tilde{\sigma} \) and the Lagrangian section \( \tilde{N} \). It remains to notice that our map \( \Phi \) in these coordinate systems, by construction, takes the form \( \tilde{H} = H, \tilde{F} = F, \tilde{t}_1 = t_1, \tilde{t}_2 = t_2 \). \( \square \)

Let \( U \subset T^2 \times B \) be an open subset such that the intersection of \( U \) with each fiber is connected and non-empty. Let \( \Phi_{\text{loc}} : U \to \tilde{U} \) be a real-analytic fiber-wise diffeomorphism with a certain open subset \( \tilde{U} \subset \tilde{T}^2 \times \tilde{B} \) such that \( \Phi_{\text{loc}}^*(\tilde{\Omega}) = \Omega \). Since \( \Phi_{\text{loc}} \) is fiberwise and \( U \) intersects each fiber, \( \Phi_{\text{loc}} \) induces a real-analytic map \( \phi \) between the bases \( B \) and \( \tilde{B} \).

**Corollary 6.4.** \( \Phi_{\text{loc}} \) can be extended up to a real-analytic fiber-wise diffeomorphism \( \Phi : T^2 \times B \to \tilde{T}^2 \times \tilde{B} \) with the property \( \Phi^*(\tilde{\Omega}) = \Omega \) if and only \( \phi : B \to \tilde{B} \) is an integer affine equivalence.
Proof. First of all we notice that such an extension (if it exists) is always unique. Indeed, since $\Phi$ is a symplectomorphism, we have
$$\Phi \circ \sigma^{(t_1,t_2)} = \tilde{\sigma}^{(t_1,t_2)} \circ \Phi,$$
where $\sigma$ and $\tilde{\sigma}$ are Hamiltonian $\mathbb{R}$-actions generated by $H, F$ and $\tilde{H} = H \circ \Phi^{-1}, \tilde{F} = F \circ \Phi^{-1}$ respectively. Therefore for any $y \in T^2 \times B$, its image $\Phi(y)$ is uniquely defined by:
$$\Phi(y) = \tilde{\sigma}^{(t_1,t_2)} \circ \Phi_{loc} \circ \sigma^{(-t_1,-t_2)}(y),$$
where $(t_1,t_2)$ are chosen in such a way that $\sigma^{(-t_1,-t_2)}(y) \in U$ (such $(t_1,t_2) \in \mathbb{R}^2$ exists as each orbit of the action $\sigma$ has a non-trivial intersection with $U$). Moreover, this formula can be understood as an explicit formula for the required extension. In a neighborhood of every point $y$, the expression $\tilde{\sigma}^{(t_1,t_2)} \circ \Phi_{loc} \circ \sigma^{(-t_1,-t_2)}$ (with fixed $(t_1,t_2)$) is a composition of three real-analytic fiberwise symplectomorphisms. So the only condition we need to check is that formula (28) is well defined, i.e., does not depend on the choice of $(t_1,t_2) \in \mathbb{R}^2$.

Assume that
$$y = \sigma^{(t_1,t_2)}(x) = \sigma^{(t_1',t_2')}(x')$$
with $x,x' \in U$.

We need to check that
$$\tilde{\sigma}^{(t_1,t_2)} \circ \Phi_{loc} \circ \sigma^{(-t_1,-t_2)}(y) = \tilde{\sigma}^{(t_1',t_2')}(x)$$
or, equivalently,
$$\tilde{\sigma}^{(t_1,t_2)} \circ \Phi_{loc}(x) = \tilde{\sigma}^{(t_1',t_2')}(x').$$

By our assumption, the intersection of $U$ with each torus (interpreted now as an orbit of $\sigma$) is connected, therefore there exists a continuous curve $(\varepsilon_1(s),\varepsilon_2(s)), s \in [0,1]$ and $\varepsilon_1(0) = \varepsilon_2(0) = 0$ such that
$$\sigma^{(\varepsilon_1(s),\varepsilon_2(s))}(x) \in U$$
for all $s \in [0,1]$ and $\sigma^{(\varepsilon_1(1),\varepsilon_2(1))}(x) = x'$.

Since $\Phi_{loc}$ is a fiberwise symplectomorphism, we have
$$\Phi_{loc} \circ \sigma^{(\varepsilon_1(s),\varepsilon_2(s))}(x) = \tilde{\sigma}^{(\varepsilon_1(s),\varepsilon_2(s))} \circ \Phi_{loc}(x)$$
for any $s$ and, in particular,
$$\Phi_{loc}(x') = \tilde{\sigma}^{(\varepsilon_1(1),\varepsilon_2(1))} \circ \Phi_{loc}(x).$$

Hence (30) can be rewritten as
$$\tilde{\sigma}^{(t_1,t_2)}(\Phi_{loc}(x)) = \tilde{\sigma}^{(t_1'+\varepsilon_1(1),t_2'+\varepsilon_2(1))}(\Phi_{loc}(x)).$$

On the other hand, since $\sigma^{(t_1,t_2)}(x) = \sigma^{(t_1',t_2')}(x')$, we also have
$$\sigma^{(t_1,t_2)}(x) = \sigma^{(t_1'+\varepsilon_1(1),t_2'+\varepsilon_2(1))}(x').$$

According to Lemma 6.2, if $\phi$ is an affine equivalence then (32) implies (31) and therefore (29), as needed.

The necessity of the condition that $\phi : B \to \tilde{B}$ is an integer affine equivalence is obvious: every fiberwise symplectomorphism induces an affine equivalence between $B$ and $\tilde{B}$. \hfill $\Box$

We now use Corollary 6.4 to prove Theorem 6.1.

Proof. First we apply Theorem 5.5 which guarantees the existence of a real-analytic fiberwise diffeomorphism $\Phi_{loc}$ \footnote{In Theorem 5.5, this map was denoted by $\Phi$.} between some neighborhoods of parabolic trajectories $\gamma_0 \subset \mathcal{L}_0$ and $\tilde{\gamma}_0 \subset \tilde{\mathcal{L}}_0$. We now need to extend $\Phi_{loc}$ up to the desired fiberwise symplectomorphism $\Phi : U(\mathcal{L}_0) \to \tilde{U}(\tilde{\mathcal{L}}_0)$.

According to Corollary 6.4 such an extension exists for all Liouville tori (more precisely, we only need to consider “wide” Liouville tori because all “narrow” Liouville tori are already contained in the domain of $\Phi_{loc}$). Thus, it remains to explain why this map can be extended by continuity to each singular fiber.

On Fig. 3 we can see the domain $U$ on which $\Phi_{loc}$ is already defined and the complementary domain $W$ to which $\Phi_{loc}$ should be extended. Without loss of generality we may assume that both domains are bounded by the sections $N_1$ and $N_2$. Namely, $U$ is located to the right of $N_1$ and $N_2$ and contains all singular orbits including the parabolic one. The complementary domain $W$ is located to the left of $N_1$ and $N_2$ and contains no singularities at all.

Let $y \in W$ be an arbitrary point located on one of singular fibers and $V(y)$ be a sufficiently small neighborhood of $y$. Then there exists $(t_1,t_2) \in \mathbb{R}^2$ such that $\sigma^{(-t_1,-t_2)}(V(y)) \subset U$ and we may apply our extension formula (29) to define $\Phi$ on $V(y)$. Obviously, this formula defines a real-analytic fiberwise (local) symplectomorphism from $V(y)$ to its image in $\tilde{U}(\tilde{\mathcal{L}}_0)$ and moreover, due to the uniqueness of such
an extension, this map coincides with Φ that has been already defined on non-singular fibers (Liouville tori). This is equivalent to saying that Φ can be naturally extended (by continuity) from Liouville tori to all singular fibers. This completes the proof. □

Remark 6.3. Our final remark is that the statement of Theorem 6.1 given in Remark 6.2 can be also understood in terms of natural affine structures defined on B and ˜B.

A necessary and sufficient condition for the existence of a semi-local fiberwise symplectomorphism Φ : U(L0) → U(L0) between neighborhoods of two cuspidal tori L0 and ˜L0 is that the corresponding bases B and ˜B are locally equivalent as manifolds with singular integer affine structures. Moreover, every affine equivalence φ : B → ˜B can be lifted up to a fiberwise symplectomorphism Φ.

Thus, our paper gives a partial answer to Problem 27 from the collection [5] of open problems in the theory of finite-dimensional integrable systems.
