Look on the bright side: The rational design and preparation of pyrene-based dipolar donor-π-acceptor fluorophores, aided by theoretical calculations, is reported. By varying the nature of the electron-donating/withdrawing substituents, the HOMO and LUMO levels can be easily tuned. These molecules exhibit large two-photon-absorption cross-sections (δ up to $2200^{\text{GM}}$ at $\lambda=780^{\text{nm}}$) and efficient two-photon brightness ($\delta\Phi$).

Two-photon absorption (TPA) properties of pyrene-based derivatives are rare as a result of the limited number of controllable synthetic methods to prepare them. However, these materials are in great demand given their potential practical application in photics and biological imaging. Herein, we present a set of pyrene-based dipolar donor-π-acceptor (D-π-A) fluorophores with a wide-range of color tuning and large TPA cross-sections (up to $2200^{\text{GM}}$ at $780^{\text{nm}}$) by regioselective substitution at the 1,3- and 6,8-positions under the perspective of theoretical analysis. The linear and nonlinear optical properties of these compounds have been studied. The near-identical emission wavelengths between the two-photon-excited fluorescence (TPEF) and one-photon excited fluorescence (OPEF) indicated that they are generated from the same fluorescent excited state by either one- or two-photon excitation. With the exception of the strong donor [N(CH$_3$)$_2$] appended fluorophore, the TPEF
exhibited a large red-shift compared with the OPEF spectra as a result of the complicated working mechanisms in operation, including intramolecular charge transfer (ICT) and twisted intramolecular charge transfer (TICT). All fluorophores exhibit high two-photon cross-sections (or two-photon brightness, $\delta\Phi$), especially for 1348^^GM, which indicated that these materials can be used as colorants for probe and bioimaging applications.

1. Introduction

Light-emitting organic conjugated molecules with large two-photon absorption (TPA) cross-sections ($\delta$) have attracted growing attention in recent decades, both at the theoretical and experimental level. This interest stems from their numerous potential applications in biologically-oriented research,[1] photodynamic therapy,[2] three-dimensional lithography/data storage,[3] and in the design of various other types of materials.[4] Within this context, developing rational strategies for the design and synthesis of molecules possessing large $\delta$ have led the trend in this field over recent years. Three basic structural motifs, namely dipolar,[5] quadrupolar,[6] and octupolar,[7] have been established, and are generalized by the construction of donor-acceptor-donor (D-A-D) type, donor-$\pi$-bridge-acceptor (D-$\pi$-A) type, donor-$\pi$-bridge-donor (D-$\pi$-D) type structures. Factors such as the geometrical parameters, including the extended $\pi$-conjugated system, the charge-transfer (CT) ability, and strength and position of electron-donating/electron-withdrawing groups influence the adoption of such motifs.[8] As well as the rapid progress on TPA, an active strategy for tuning the CT ability of prepared molecules with a desired TPA activity has been sought. In general, the high sensitivity of various vibrations to electronic density plays a crucial role on their TPA properties.[8c] Thus, a facile approach to prepare new charge-transfer molecules with tailored band gaps ($\Delta E_g$) by introducing donor and acceptor groups was developed. Donors can provide a significant contribution to the high lying occupied molecular orbitals because they are prone to donate electrons. Acceptors on the other hand have an effect on the low lying unoccupied molecular orbitals because they are prone to accept electrons (Scheme$^{^\wedge}1<$sch1$>$).[9] In the case of donor-acceptor (D-A) structures, the energy gap of the new materials can be significantly tuned compared with the parent components.
One class of polycyclic aromatic hydrocarbons (PAHs) with a large \( \pi \)-conjugated core, excellent photoluminescence efficiency and deserving of particular attention is pyrene.\textsuperscript{[10]} To date, pyrene-based fluorophores with TPA properties remain rare; examples include dipolar/quadrupolar molecules,\textsuperscript{[11]} and multi-branch structural molecules.\textsuperscript{[12]} Given this, the construction of pyrene-based D-\( \pi \)-A TPA materials with considerable \( \delta \) values (even more than 1000 GM) is a promising strategy when pyrene is employed as the \( \pi \)-core. The previous studies have shown that donor/acceptor substituted pyrene-based derivatives can exhibit novel and tunable photophysical properties.\textsuperscript{[13]} On the other hand, we also predicted that unsymmetrical D-\( \pi \)-A pyrene-based derivatives will possess efficient TPA properties. Taking account of the above considerations, by introducing different electron-donating/withdrawing substituents, a series of pyrene-based dipolar molecules, with tunable LUMO and HOMO levels and large \( \delta \) value are reported (Scheme\textsuperscript{2}). Insight into the structure-property relationships of one-photon absorption and TPA of the five molecules reported herein was obtained by combining experimental and theoretical results, and evaluating the influence of donor and acceptor groups.

2. Results and Discussion

The synthetic procedure for 2 is outlined in Scheme\textsuperscript{2}, and was designed to gradually modulate the energy levels by changing the substituents. Thus, a set of pyrene-based dipolar molecules 2 were synthesized in high yield by the Pd-catalyzed coupling reaction of the precursor 1,3-diphenyl-6,8-dibromopyrene 1.\textsuperscript{[13]a} The structures and high purity were unambiguously confirmed by \( ^1\text{H} / ^{13}\text{C} \) NMR spectroscopy, high-resolution mass spectrometry (HRMS) and X-ray crystallography. The detailed synthetic procedures and characterization data are given in the Supporting Information (Figures\textsuperscript{S1--S10\dagger}). All compounds exhibited good solubility in common organic solvents and exhibited excellent thermal stability.

Single crystals of 2b, 2c and 2e were obtained from chloroform/hexane mixtures by the slow solvent evaporation method, and were analyzed by single crystal X-ray diffraction crystallography using synchrotron radiation. As depicted in Figure\textsuperscript{1}, Table\textsuperscript{S1,}
and Figures S11--S13, in case of 2b and 2e, the two para-substituted rings are almost co-planar with the pyrene moiety, while the two phenyl groups are more substantially twisted in all three X-ray structures. The dihedral angles between the para-substituted rings and the pyrene core (C1>C16) are 17.03(6)° (C39>C44), 7.97(6)° (C31>C36) for 2b, and 9.51(9)° (C41>C46), 9.07(9)° (C31>C36) for 2e. The twist angles between the pyrene core and the following phenyl groups are 47.18(4)° (C17>C22), 62.78(3)° (C23>C28) for 2b, and 55.13(6)° (C17>C22), 58.93(6)° (C23>C28) for 2e. It is worth noting that the NMe2 para substituents of 2e effectively weaken the π–π stacking interaction due to the twist angles between the C6 aromatic ring and the NMe2 groups, 15.0(3)° (C31>C36 and N1/C37/C38), 34.8(2)° (C41>C46 and N2/C47/C48). For 2c, there are four molecules of the pyrene plus one molecule of chloroform in the unsymmetrical unit. The twist angles (°) between the pyrene core and phenyl groups and C6H4 rings beyond the alkyne linkage are summarized in Table S2. In summary, the dihedral angles between the para-substituted rings beyond the alkyne linkage exhibit one shallow angle (range 0.16--8.61(19)°) and one more twisted angle (range 42.38--49.55(11)°) with respect to the pyrene core, while the phenyl rings are all significantly twisted (range 41.23--58.54(14)°).

A detailed investigation indicated that the molecular packing of 2b, 2c, and 2e displayed marked differences. For 2b, molecules pack in layers with zones of interdigitated phenyl groups and a separate zone of interdigitated F-substituted aromatic rings (Figure 2a). Molecules form off-set face-to-face π⋯π stacks with the center of the pyrene overlaying the alkyne group C(29)/C(30) in a neighboring molecule at a distance in the range 3.339--3.355 Å (depicted as orange dashed lines), and edge-to-face ArC<⋯H⋯π interactions between the edge of the phenyl groups and the pyrene core at distances of 2.704 and 2.880 Å (Figure 2b bottom, depicted as blue dashed lines). For 2c, as shown in Figure 2c, 2d, the chloroform molecule either forms a C<⋯H⋯π interaction with ring C(17)>C(22) or with a symmetry generated ring C(23B)>C(28B). Meanwhile, the molecules stack in slipped columns parallel to a with pyrene cores only just overlapping. Similar π⋯π stacks with the center of the pyrene or C6H4 rings overlaying the alkyne group at a distance in the range 3.346--3.390 Å were observed. On the other hand, for 2e, the more
twisted conformations associated with the para-substituents can alleviate the intermolecular \( \pi \rightarrow \pi \) stacking interactions to some degree, and instead they overlay with one of the alkyne groups C(39)/C(40) of a neighboring molecule. This off-set stacking occurs parallel to \( b \). The closest C⋯C interactions are ca. 3.42 Å. There are also rather distorted centro-symmetric pairs of ArC-(24)--H(24)⋯π \{centroid of ring C(41)>C(46)\} interactions with a short distance of 2.59 Å (Figure 2f, blue dashed lines). These results demonstrate that compared with the F-substituted analog \( 2b \), the \( \pi \rightarrow \pi \) stacking interactions between the NMe2-substituted molecules are substantially weakened due to the bulky para substituent, which should favor tunable emission properties in solution with more substantially twisted structures.

Initially, density functional theory (DFT) calculations were performed to evaluate the energy levels of this type of dipolar molecule at the B3LYP/6-31G* level. As depicted in Figure 3, the energy gaps gradually reduce from \( 2a \) to \( 2e \), which further indicated that this strategy to tune the LUMO and HOMO levels is an efficient process. Compared with the compound 1,3-diphenylpyrene (3.58 eV), compounds \( 2 \) exhibited distinctly lower energy gaps, which is due to the introduction of donor or acceptor groups at the 6-, and 8-positions. Compared with \( 2a \), the energy gaps of the other four compounds \( 2b \rightarrow 2e \) also gradually reduce, which is associated with the donating- or withdrawing-electron ability of the substituents (\( R \)) at the para-position of arylethynyl. Specifically, relative to \( 2a \) (\( R<=>H \)), \( 2b \) (\( R<=>F \)) and \( 2c \) (\( R<=>OMe \)), the substituent groups at the 6-, and 8-positions are weakly electron-withdrawing/donating substituents, respectively, and provide a certain degree of influence over the LUMOs and HOMOs. For compound \( 2d \) (\( R<=>CHO \)), the terminal substituent is a strong electron-withdrawing group, and so it provided energetically enhanced LUMOs, which are mainly distributed over the pyrene core and arylethynyl substituents. On the contrary, the HOMOs of compound \( 2e \) (\( R<=>N(CH_3)_2 \)), with strong electron-donating substituents, are mostly localized on the pyrene core and arylethynyl substituents. This implies that the HOMOs and LUMOs are determined by the terminal substituents \( R \). Theoretical studies indicate that there are several effective strategies to improve the TPA cross-sections, such as highly delocalized conjugated system, increased intramolecular charge transfer character, and multi-branched molecular structures. Consequently, in our present
systems, the extended conjugated D-π-A molecules with ICT character along the long axis were predicted that they possess TPA properties, especially for compounds 2d and 2e.

Further investigations of the UV-vis absorption and emission properties were performed for compounds 2 based on our preliminary theoretical guidance, and the key spectroscopic parameters are summarized in Table 1. As shown in Figure 4a, the absorption spectra of 2 in dichloromethane are distinctive but complicated, which is attributed to the D-π-A type molecular structures and the extended π-conjugated system. A gradual bathochromic shift was observed in the order 2a ≈ 2b < 2c < 2d < 2e, indicating the increasing tendency of intramolecular charge transfer (ICT). On the other hand, the type of absorption profiles present obvious distinctions, especially for 2d and 2e, the more tunable and sensitive absorption properties are mainly associated with the extent of ICT and twist intramolecular charge transfer (TICT). Specifically, for 2a--2e, three sets of pronounced absorption bands were observed. Firstly, a short-wavelength band distributed in less than 250 nm which is mainly due to the π-π* transitions of the phenyl groups and the pyrene core. Secondly, a long-wavelength band localized in the range of 409--434 nm with high molar absorption coefficients (53100--70100 cm−1 M−1), and lastly an absorption band mainly centered at 318--336 nm with higher values for the molar absorption coefficients (49600--82800 cm−1 M−1). However, more obvious and complicated characteristic absorption bands were noted for 2d and 2e. In particular, new absorption bands at 367 nm with a low value of ε (39800 cm−1 M−1) for 2d, and at 388 nm with a low value of molar absorption coefficients (52300 cm−1 M−1) for 2e were observed, respectively. The results of the above mentioned results for compounds 2 indicate that their excited states possess significant charge transfer (CT) absorption associated with the withdrawing- or donating-electron peripheral unit at the 6,8-diarylethynyl terminal substituents in these D-π-A systems.

In contrast, the fluorescence spectra of compounds 2 exhibit a clear and simple emission band, the emission maxima are in the range 452--532 nm in CH2Cl2 solution (c=5×10−7 M) with a sequential bathochromic shift in the order 2a ≈ 2b < 2c < 2d < 2e (Figure 4b). This is highly consistent with the energy gaps from the DFT
calculation results; the energy gap ($E_g$) between the Franck-Condon and emitting state decreases in the same order. As expected, combined with the theoretical calculations, slight bathochromic shifts ($<5^{\text{nm}}$) between 2a--c were observed, while 2d--f exhibited a distinct bathochromic shift ($33^{\text{--}80^{\text{nm}}}$) compared with the former. To further elucidate the emission mechanism of this D-π-A system, solvatochromism was performed in solvents of different polarities (cyclohexane, CHX; 1,4-dioxane, DOA; tetrahydrofuran, THF; dichloromethane, DCM; and dimethyl formamide, DMF). The absorption properties of this set of compounds 2 displayed different sensitivities for the polarity. For compounds 2a--2d, they present almost identical absorption spectra from cyclohexane to DMF (less than $4^{\text{nm}}$ red-shifts). On the other hand, for compound 2e, a large red-shift ($12^{\text{nm}}$) and change of absorption bands were observed from cyclohexane to DMF, which is ascribed to the TICT of twist geometry. As shown in Figure 5 and the Supporting Information (Figure S15), the fluorescence spectra of this set of compounds are sensitive toward to the solvent polarity, especially for 2e, where the emission maximum displayed a remarkable red-shift on increasing the solvent polarity (cyclohexane $470^{\text{nm}}$, DMF $582^{\text{nm}}$). And the weak emission band as a shoulder at long wavelength indicated that there may be a TICT state in cyclohexane, with the increase of solvent polarity, the CT emission and local emission are overlap. The relationship between the Stokes shifts in various solvents and the Lippert-Mataga equation was investigated,[16] and a nearly linear correlation between these two factors was evident (Figure 5b). The slopes of the linear fits for compounds 2a--e are 16, 14, 17, 80 and $569^{\text{cm}^{-1}}$, respectively, which indicates an increasing trend for the charge transfer.[17] Concentration dependent experiments were carried out in CH2Cl2 solution successively, and the emission properties of these compounds are consistent with the X-ray structural information. Taking compound 2b as an example, the emission spectra exhibited a wide peak at $452^{\text{nm}}$ with a shoulder at $478^{\text{nm}}$ in dilute solution, and the shoulder band has gradually become domination with increase of concentration, which results from the formation of excimer. The fluorescence quantum yields and emission decay profiles of the compounds 2 are shown in Table 1. All compounds exhibit high quantum yields ($\geq0.75$) and considerably short lifetimes ($\leq15^{\text{ns}}$) at room temperature (Figure S17). The same prompt and delayed
PL emissions readily reveals the emission state resulting from the lowest singlet excited state.\[18\]

The two-photon absorption (TPA) spectra of the five compounds 2 were studied using a two-photon-excited fluorescence (TPEF) technique with a femtosecond pulsed laser source.\[19\]

TPA cross sections (\(\delta\)) have been measured using the two-photon induced fluorescence method,\[20\] and thus the cross section can be calculated by means of Equation\(^{(1)}\):

\[
\delta_s = \frac{\delta_r \Phi c_s n_s F_s}{\Phi c_r n_r F_r} <ZS>(1)
\]

where the subscripts \(s\) and \(r\) refer to the sample and the reference materials, respectively. \(\delta\) is the TPA cross section value, \(c\) is the concentration of the solution, \(\Phi\) is the fluorescence quantum yield, \(F\) is the two-photon excited fluorescence integrated intensity, and \(n\) is the refractive index. \(\delta_r\) is the two-photon absorption cross-section of fluorescein in sodium hydroxide aqueous solution (pH=13.0) as the standard.\[21\]

The TPA spectra of a series of compounds 2 were performed in DMSO solution at 20\(^\text{nm}\) intervals from 780 to 900\(^\text{nm}\) by using a femtosecond pulsed laser source. The TPA spectra of compounds 2 are presented in Figure\(^6\). Depending on the extended \(\pi\)-conjugation and intramolecular charge-transfer over the entire molecule, all the compounds displayed large TPA cross-sections \(\delta_s\), (\(\delta\), expressed in GM=10\(^{\text{M} - 5\text{GM} \cdot 4\text{cm}^2 \cdot \text{S} \cdot \text{photon} \cdot \text{M}^{-1} \cdot \text{molecule}^{-1}\)). The \(\delta_s\) values, 202 GM for 2a at 780\(^\text{nm}\), 172\(^\text{GM}\) for 2b at 780\(^\text{nm}\), 73 GM for 2c at 800\(^\text{nm}\), 1450\(^\text{GM}\) for 2d at 780\(^\text{nm}\), 2210\(^\text{GM}\) for 2e at 780\(^\text{nm}\), are reasonable compared with other reported functionalized pyrene-based small molecules. Especially for 2d (1450\(^\text{GM}\)) and 2e (2210\(^\text{GM}\)), the \(\delta_s\) values are large by comparison with other small pyrene-based molecules reported to date,\[11\] indicating that the extended \(\pi\)-conjugation and increased ICT behavior are favorable features to access high-efficiency organic molecules with large \(\delta\) values. Moreover, the performance of two-photon active fluorescent molecules is generally evaluated according to the value of the two-photon action
cross sections ($\delta \times \Phi$), which are an indicator of the brightness of the emission process. In this type of molecule, the $\delta \Phi$ values for 2d (1348 GM) and 2e (641 GM) are distinctly large compared with the values for other pyrene-based TP active fluorescents. Although the trend in the $\delta_s$ values are not exact consistent with the abilities of intramolecular charge transfer from 2a to 2e, as one of the critical factors, theoretical results indicated that strong electron-withdrawing (2d) and electron-donating (2e) groups play a leading role in TPA properties. This result implies that pyrene as an efficient $\pi$-center may serve as a promising two-photon imaging material for various applications.\[22\]

Apart from TPA properties, the two-photon excited fluorescence (TPEF) of 2 was also studied under the same experimental conditions ($\lambda_{ex}=780$ nm). As shown in Figure\(^7\) and Table\(^1\), the spectral profiles for the TPEF are basically identical to the one-photon excited fluorescence (OPEF) except for 2e. The similarities between the TPEF and OPEF indicated that they would finally relax to the same fluorescent excited state by either one- or two-photon excitations. Thus, for compounds 2a--d, it seems to be impartial to the influence of the TPEF and OPEF properties except for a slight red-shift (no more than 5 nm). On the other hand, the different spectral selection rules for TPA and one-photon absorption (OPA) processes can lead to different excited states in these two cases.\[23\]
For compound 2e, a large red-shift (49 nm) was observed, and we assume that the distinction results from the reabsorption effect.\[24\] The effect occurs at high concentration; (10$^{-5}$ mol/L for the measurement of TPEF, and 10$^{-7}$ mol/L for the measurement of OPEF). Furthermore, such red-shifted emission spectra can be ascribed to the different emitting states accessed by one- or two-photon excitation.\[25\]

Presented here, the OPEF and TPEF properties combined with theoretical calculations indicate that D-$\pi$-A pyrene systems exhibit excellent tunability for the design of large TPA cross sections and two-photon action cross sections. This type of molecule is not only a promising OPEF activator, but also an efficient TPEF fluorophore.

3. Conclusions
In conclusion, we have demonstrated an efficient and facile strategy for the
design and synthesis of D-π-A pyrene-based fluorophores with large TPA cross section,
which benefit from theoretical guidance. A microscopic rule was employed to prepare
a series of dipolar molecules with graded energy gaps. Aided by this method, the first
element of small pyrene-based dipolar molecules with δ above 2200^GM is reported,
which can be attributed to the strong electron-donating nature of the <C->N(CH₃)₂ groups
present. The electron-withdrawing nature of the <C->CHO groups results in a dipolar
molecule with high quantum yield (93^%) and large TP action cross section (1348^GM).
Such OPEF and TPEF properties indicate a promising application in two-photon imaging
materials. More studies are necessary to understand the underlying mechanisms of this
type of molecule, and further detailed investigations are aimed at developing such TPA
fluorophores in our laboratory.

Experimental Section

General Procedures

Synthetic routes for the five compounds 2 are shown in Scheme<xschr2>. All reactions
were carried out under a dry N₂ atmosphere. Solvents were Guaranteed reagent (GR) for cyclohexane,
1,4-dioxane, tetrahydrofuran (THF), dichloromethane (CH₂Cl₂), dimethylformamide (DMF), and
dimethyl sulfoxide (DMSO), and stored over molecular sieves. Other reagents were obtained
commercially and used without further purification. Reactions were monitored using thin layer
chromatography (TLC). Commercial TLC plates (Merck Co.) were developed and the spots were
identified under UV light at 254 and 365^nm. Column chromatography was performed on silica gel
60 (0.063–0.200^mm). All melting points (Yanagimoto MP<S->S1) are uncorrected. ^H/^{13}C NMR
spectra were recorded on a Varian-400MR-vnmrs 400 with SiMe₄ as an internal reference. Mass
spectra were obtained with a Nippon Denshi JMS-HX110^A Ultrahigh Performance mass
spectrometer at 75^eV using a direct-inlet system. UV/ Vis spectra were obtained with a Perkin-
Elmer Lambda 19 UV/Vis/NIR spectrometer in various organic solvents. Fluorescence spectroscopic
studies were performed in various organic solvents in a semi-micro fluorescence cell (Hellma®, 104F-
Experimental Details

Synthesis of 1,3-Diphenyl-6,8-diarylethynylpyrenes (2a--e)

A series of compounds 2a--e were synthesized from 1,3-diphenyl-6,8-dibromopyrene 1 using the corresponding aryl alkyne by a Sonogashira coupling reaction.

1,3-Diphenyl-6,8-bis-(phenylethynyl) pyrene (2a)

A mixture of 1,3-diphenyl-6,8-dibromopyrene 1 (102 mg, 0.2 mmol), phenylacetylene (82 mg, 0.8 mmol), PdCl₂(PPh₃)₃ (14 mg, 0.02 mmol), CuI (7.6 mg, 0.04 mmol), PPh₃ (5 mg, 0.02 mmol) was added to a degassed solution of Et₃N (5 mL) and DMF (5 mL). The resulting mixture was stirred at 100°C for 24 h. After it was cooled to room temperature, the reaction was quenched with water. The mixture was extracted with CH₂Cl₂ (2×500 mL), the organic layer was washed with water (2×30 mL) and brine (30 mL), and then the solution was dried (MgSO₄), and evaporated. The residue was purified by column chromatography eluting with a 1:3 CHCl₃/hexane mixture to give 2a as an orange solid (recrystallized from hexane:CHCl₃=4:1, yield: 95 mg, 81.2%; Mp 195--196°C; ¹H NMR (400 MHz, CDCl₃): δ_H=7.41 (d, J=7.3 Hz, 6H, Ar-H), 7.47--7.52 (m, 2H, Ar-H), 7.57 (t, J=7.3 Hz, 4H, Ar-H), 7.68 (d, J=6.3 Hz, 8H, Ar-H), 8.04 (s, 1H, pyrene-H), 8.35 (d, J=9.4 Hz, 2H, pyrene-H), 8.45 (s, 1H, pyrene-H), 8.64 (d, J=9.4 Hz, 2H, pyrene-H) ppm; ¹³C NMR (100 MHz, CDCl₃): δ_C=88.0, 95.4, 117.7, 123.4, 124.9, 125.1, 125.5, 127.0, 127.5, 128.2, 128.5, 128.5, 130.0, 130.6, 130.7, 131.7, 132.0, 133.4, 138.6, 140.7 ppm; FAB-MS: m/z calcd for C₄₄H₂₆ 554.2037 [M⁺]; found 554.2035 [M⁺].

A similar procedure using phenylacetylene, 4-fluorophenyl acetylene, 4-methoxyphenyl acetylene, 4-formylphenyl acetylene, was followed for the syntheses of 2b--e.

1,3-Diphenyl-6,8-bis-(4'-fluorophenylethynyl) pyrene (2b) was obtained as a yellow solid (recrystallized from hexane:CHCl₃=3:1, yield: 115 mg, 63.6%; Mp 263--264°C; ¹H NMR (400 MHz, CDCl₃): δ_H=7.12 (t, J=8.1 Hz, 4H, Ar-H), 7.47--7.52 (m, 2H, Ar-H), 7.57 (t, J=7.0 Hz, 4H, Ar-H), 7.67 (t, J=7.1 Hz, 8H, Ar-H), 8.05 (s, 1H, pyrene-H), 8.35 (d, J=9.4 Hz, 2H, pyrene-H).
2H, pyrene-H), 8.41 (s, 1H, pyrene-H), 8.60 (d, J=9.4^\text{Hz}, 2H, pyrene-H) ppm; $^{13}$C NMR (100^\text{MHz}, CDCl$_3$): $\delta_{C}=87.7, 94.4, 110.1, 115.76, 116.0, 117.5, 119.5, 125.1, 125.4, 127.2, 127.6, 128.2, 128.5, 130.1, 130.7, 132.1, 133.3, 133.6, 133.6, 138.7, 140.7, 161.5^\text{ppm};$ FAB-MS: m/z caled for C$_{44}$H$_{24}$F$_2$ 590.1846 [M$^+$]; found 590.1844 [M$^+$].

1,3-Diphenyl-6,8-bis-(4'-methoxyphenylethynyl) pyrene (2c) was obtained as a pale-yellow solid (recrystallized from hexane:CH$_2$Cl$_2=2^\text{:}:1$, yield: 107^\text{mg}, 58.2^\%); Mp 169--170°C; 1H NMR (400^\text{MHz}, CDCl$_3$): $\delta_{H}=3.87$ (s, 6H, Me), 6.95 (d, J=7.0^\text{Hz}, 4H, Ar-H), 7.47--7.52 (m, 2H, Ar-H), 7.57 (t, J=7.3^\text{Hz}, 4H, Ar-H), 7.63 (d, J=6.9^\text{Hz}, 4H, Ar-H), 8.03 (s, 1H, pyrene-H), 8.33 (d, J=9.4^\text{Hz}, 2H, pyrene-H), 8.41 (s, 1H, pyrene-H), 8.63 (d, J=9.4^\text{Hz}, 2H, pyrene-H) ppm; $^{13}$C NMR (100^\text{MHz}, CDCl$_3$): $\delta_{C}=54.5, 85.9, 94.6, 113.3, 114.6, 117.1, 124.1, 124.2, 124.6, 125.8, 126.6, 127.3, 127.5, 129.0, 129.8, 130.7, 132.1, 133.7, 137.4, 139.8, 158.9^\text{ppm};$ FAB-MS: m/z caled for C$_{46}$H$_{30}$O$_2$ 614.2246 [M$^+$]; found 614.2248 [M$^+$].

1,3-Diphenyl-6,8-bis-(4'-formylphenylethynyl) pyrene (2d) was obtained as an orange solid (recrystallized from hexane:CHCl$_3=1^\text{:}:1$, yield: 107^\text{mg}, 65.5^\%); Mp 177--178°C; 1H NMR (400^\text{MHz}, CDCl$_3$): $\delta_{H}=7.49--7.54$ (m, 2H, Ar-H), 7.58 (t, J=7.6^\text{Hz}, 4H, Ar-H), 7.68 (d, J=8.0^\text{Hz}, 4H, Ar-H), 7.81 (d, J=7.9^\text{Hz}, 4H, Ar-H), 7.92 (d, J=7.6^\text{Hz}, 4H, Ar-H), 8.08 (s, 1H, pyrene-H), 8.39 (d, J=9.4^\text{Hz}, 2H, pyrene-H), 8.46 (s, 1H, pyrene-H), 8.60 (d, J=9.4^\text{Hz}, 2H, pyrene-H) ppm; $^{13}$C NMR (100^\text{MHz}, CDCl$_3$): $\delta_{C}=91.9, 94.6, 110.0, 116.7, 125.1, 127.7, 127.9, 128.0, 128.5, 129.7, 130.2, 130.5, 130.7, 132.1, 132.7, 133.7, 135.6, 139.2, 140.4, 191.3^\text{ppm};$ FAB-MS: m/z caled for C$_{46}$H$_{30}$O$_2$ 610.1934 [M$^+$]; found 610.1933 [M$^+$].

1,3-Diphenyl-6,8-bis-(4'-N, N-dimethylphenylethynyl) pyrene (2e) was purified by column chromatography eluting with a 2^\text{:}:1 CH$_2$Cl$_2$/hexane mixture to give 2e as a red granular solid (yield: 159^\text{mg}, 81.5^\%); Mp 297--298°C; 1H NMR (400^\text{MHz}, CDCl$_3$): $\delta_{H}=3.03$ (s, 12H, Me), 6.73 (d, J=8.0^\text{Hz}, 4H, Ar-H), 7.46--7.51 (m, 2H, Ar-H), 7.53--7.59 (m, 8H, Ar-H), 7.68 (d, J=6.9^\text{Hz}, 4H, Ar-H), 8.00 (s, 1H, pyrene-H), 8.28 (d, J=9.4^\text{Hz}, 2H, pyrene-H), 8.38 (s, 1H, pyrene-H), 8.64 (d, J=9.4^\text{Hz}, 2H, pyrene-H) ppm; $^{13}$C NMR (100^\text{MHz}, CDCl$_3$): $\delta_{C}=40.2, 86.3, 96.9, 110.3, 112.0, 118.8, 125.2, 125.2, 125.8, 126.1, 127.4, 128.3, 128.4, 129.8, 130.7, 131.1, 132.7, 132.9, 138.0, 141.0, 150.3^\text{ppm};$ FAB-MS: m/z caled for C$_{48}$H$_{36}$N$_2$ 640.2878 [M$^+$]; found 640.2870 [M$^+$].
X-ray Crystallography

Suitable single crystals of 2b, 2c and 2e were obtained from solution of chloroform/hexane (2:1), respectively. Diffraction data was collected at the ALS, beam line 11.3.1, using silicon 111-monochromated synchrotron radiation (\(\lambda=0.7749\AA\)). Data were corrected for Lorentz and polarisation effects and for absorption from multiple and symmetry equivalent measurements.\(^{[26]}\) The structures were solved by a charge flipping algorithm and refined by full-matrix least-squares methods on \(F^2\).\(^{[27]}\) For 2c the absolute structure could not be reliably determined due to the lack of a heavy atom. In 2e the chloroform molecule was positionally disordered over two sets of positions with major component occupancy of 62.5(5)\(^{\%}\). There was some evidence of low occupancy second component disorder in several of the Ph and C\(_6\)H\(_4\) rings and the OMe groups, but this was not modelled.

CCDC\(^{[28]}\)1812898--1812900 contain the supplementary crystallographic data for this paper. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: 144-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk].

Acknowledgements

This present work was performed under the Cooperative Research Program of “Network Joint Research Center for Materials and Devices (Institute for Materials Chemistry and Engineering, Kyushu University)”. We would like to thank the OTEC at Saga University and the International Cooperation Projects of Guizhou Province (No. 20137002) for financial support and the EPSRC for an overseas travel grant to C.R. The Advanced Light Source is supported by the Director, Office of Science, Office of Basic Energy Sciences, of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

[a] Measured in dichloromethane at room temperature. [b] Stokes shift. [c] Measured in DMSO at room temperature. [d] The \(\delta\) value represents the two-photon absorption cross sections determined using fluorescein (\(\Phi_{\text{fl}}=0.95\)) as the standard,\[^{[15]}\] ±15^\%. [e] \(\delta \times \Phi\) is the two-photon action cross-section.
