ABSTRACT

New systems for catalytic asymmetric epoxidation

Phillip Parker

Key Words: Epoxidation, Alkene, Asymmetric Synthesis, Iminium salt, Oxaziridinium salt, Oxone, Hydrogen Peroxide, Sodium Hypochlorite, Oxidation, Organocatalysis, Catalysis

This thesis describes the catalytic asymmetric epoxidation of olefins mediated by chiral iminium salts. The first chapter introduces some of the most novel and effective catalytic asymmetric methods for preparing chiral oxiranes.

The second chapter is divided into three sections. The first section of chapter two is dedicated to our efforts to develop new aqueous oxidative conditions using both hydrogen peroxide and sodium hypochlorite as efficient, green oxidants that remove the temperature boundaries observed with the use of Oxone® as the stoichiometric oxidant. A wider range of available temperatures was examined allowing optimization of both oxidative systems. Ethereal hydrogen peroxide was observed to mediate asymmetric epoxidation within an acetonitrile monophasic co-solvent system giving enantioselectivities of up to 56%. When sodium hypochlorite was used in a biphasic solvent system in conjunction with dichloromethane; it was observed to mediate oxidation of the substrate alkenes in up to 71% ee.

The second and third sections of chapter two are dedicated to our efforts to synthesize chiral iminium salts as catalysts for asymmetric epoxidation based on a biphenyl azepinium salt catalyst structure.

From previous work within the Page group, the asymmetric synthesis and subsequent defined stereochemistry of a chiral carbon atom \( \alpha \) to the iminium nitrogen atom was shown to have significant effect on the enantiocontrol of epoxidation using the iminium salt catalyst. Work was completed on biphenyl azepinium salt catalysts, inserting an alkyl or aryl Grignard reagent into the iminium bond using a pre-defined dioxane unit as a chiral auxiliary. Oxidation of the subsequent azepine gave a single diastereoisomerically pure azepinium salt. The methyl analogue of this sub-family of azepinium catalysts has been shown to give up to 81% ee for epoxidation of 1-phenylcyclohexene, furthermore, the binaphthalene azepinium salt with an additional methyl group was also synthesized and was shown to give up to 93% for epoxidation of 1-phenylcyclohexene.

Continuation of the substitution \( \alpha \) to the nitrogen atom gave rise to an interesting tetracyclic (biphenyl) azepinium salt catalyst. Construction of an asymmetric oxazolidine ring unit encapsulating the azepinium nitrogen and one of the methylene carbon atoms was achieved. In doing so two chiral centres \( \alpha \) to the nitrogen atom were generated. The azepinium chiral carbon atom was populated by an addition methyl group with variation in the substitution on the oxazolidine chiral carbon atom. The benzyl analogue of this sub-family of tetracyclic azepinium catalysts has shown to give up to 79% ee for epoxidation 1-phenylcyclohexene.

The third chapter is the experimental section and is dedicated to the methods of synthesis and characterization of the compounds mentioned in the previous chapter.

X-ray reports regarding the crystallographic analysis of the structures presented in chapter two are provided in appendix A. Appendix B contains the analytical spectra for the determination of enantiomeric excess of the epoxides.
Firstly I should like to thank Professor Philip Page for supervising me over the last six years, starting with two undergraduate summer placements moving swiftly into a three-year postgraduate placement. I feel honoured that he took the time to teach me and gave me every opportunity to progress myself, my education and my career as an organic chemist.

I must also thank the following; Dr Benjamin Buckley for being there, all of the time, with answers to relentless enquiries and problems; Dr Gerasimos Rassias at GlaxoSmithKline in Stevenage for the generous offer of the CASE award placement, for looking after me over the duration of my placement and for taking the time to teach me, not just chemistry, but more significantly in how to act as a professional organic chemist in the industrial world; Loughborough University for their financial support.

I should like to thank Dr Mark Edgar for the NMR service that is constantly under threat from inorganic attack and the constant supply of beer tokens. Mr (James) Alistair Daley for teaching me every trick from the “GC manual for dummies” and getting the chiral GC-FID in workable state. Mr John Kershaw for the amazing amount of mass spectrometry samples he has worked though with ridiculous short notice. And finally Dr Mark Elsegood for the top rate X-ray crystallography service he provides.

I wish to thank all of the members of the Page group past and present who have helped me in many ways throughout my postgraduate studies; Celine, Yohan, Claire E, Farah, Giovanni, Claire G, Colin, Julien, Amber, Claire L, Matt, Genna, Andy, KC and Louise.

I should also like to thank all of my lab colleagues who have helped me through the emotional highs and lows of lab life; Eric, Jamie, Craig, Liam, Sean, Carol, Vinny, Laura, Toby and Adam.

I’d also like to thank my ‘library’ partners “Young” Paul and Andy “Van Halen”.

I thank my parents, Julie and Nigel for the continual support, both economic and emotional, throughout my entire university education, and for supporting my decisions whether good or bad. To my brother Neil for putting up with me and for the support he has given me over the last two years.

And finally I should like to thank my amazing wife Rachel for her patience and love; without her support I can honestly say I would not be the person I am today, I would not be in a position to submit my thesis as I do now. Thank you for giving me a beautiful son, Reece, you are my rock on which I depend, I love you.

Chapter One:
Introduction
1 Introduction

“The universe is dissymmetrical; for if the whole of the bodies which compose the solar system were placed before a glass moving with their individual movements, the image in the glass could not be superimposed on reality………… Life is dominated by dissymmetrical actions. I can foresee that all living species are primordially, on their structure, in their external generates functions of cosmic dissymmetry.”

– Louis Pasteur, 1848

1.1 Asymmetric synthesis

Louis Pasteur identified that all living organisms, as well as the molecules they house, can be ‘dissymmetrical’. Dissymmetry, or asymmetry is the lack of equivalence between two objects, this is the case for carbon atoms containing four in–equivalent groups. The central carbon atom is deemed chiral and chirality is one of the most fundamental concepts in chemistry.

Chiral comes from the Greek word ‘cheir’ which in English translates as ‘hand’. A pair of hands are mirror images of one another, they cannot be superimposed. Chiral molecules also behave in this way. Molecule 1 can be reflected in a mirror and observed as a molecule identical to 2. Both 1 and 2 have identical physical and chemical identities, melting point, boiling point and molecular weight etc, all except their conformation in space. This means that 1 cannot be superimposed on 2. Molecules exhibiting this characteristic such as 1 and 2 are named enantiomers, the central carbon atom in each molecule is deemed chiral.
The general nomenclature for two enantiomers at a chiral carbon atom is the $R$ and $S$ notation. $R$ is the notation for *rectus*, Latin for right and $S$ is the notation for *sinister*, Latin for left. Figures 3 and 4 are an example of $R$ and $S$ enantiomers. The notation of each chiral carbon is denoted via the Cahn–Ingold–Prelog rules; the atom with the lowest atomic number attached to the central carbon is held furthest from the eye through the central carbon atom, the three remaining atoms are ranked A, B and C by the value of its atomic number (high to low). The $R$ enantiomer, 3, has the configuration that rotates clockwise through the three largest atoms, whereas the $S$ enantiomer, 4, rotates through the same atoms in an anti–clockwise direction.2

![Diagram of R and S enantiomers](image)

In the human body, enantiomers may work as independent chemical entities to one another as they can be absorbed, activated and degraded in different ways and at different rates. Cell membranes and enzymes in the human body contain protein receptors made of chiral amino acids.1 The chiral receptors operate using a “lock and key” mechanism, in which the receptors are able to distinguish between individual enantiomers and they preferentially interact with the enantiomer that has the desired chirality, fitting together as a “lock and key”. This allows the receptor to initialise a chemical process, a bodily function or initiate therapeutic effects. If the chiral receptor were to interact with the opposite enantiomer no response may occur, but ultimately a detrimental response may also occur. Therefore the preferred enantiomer can show increased activity over its enantiomer, whether it be higher levels of therapeutic effectiveness or oppositely higher levels of toxicity.1

Two examples of chiral drug recognition are $L$-DOPA and $R$–thalidomide. Emil Fischer devised the $D$ and $L$ nomenclature when attempting to identify unknown enantiomers of common amino acids and sugars. He portrayed glyceraldehyde in its Fischer projection and gave each enantiomer a notation: the (+)-enantiomer was labelled $D$ for *dextro* and
the (−)-enantiomer was labelled \(L\) for *laevo*. In 1951 it was proven that the \(D\) enantiomer actually had the \(R\) absolute configuration, and consequently \(L\) was \(S\).\(^1\)

\(L\)-DOPA, 1, is used in the treatment of Parkinson’s disease. \(L\)-DOPA is administered into the body as a ‘pro-drug’ as dopamine itself cannot cross the blood brain barrier.\(^3\) When \(L\)-DOPA is taken into brain cells it is automatically converted to dopamine by enzyme catalysed *in–vivo* decarboxylation. The enzyme used is \(L\)-DOPA decarboxylase; this is a chiral enzyme and enantiomer specific; it will not convert \(D\)-DOPA, 2, into dopamine. Therefore the administration of DOPA must be exclusively in the \(L\) form, as the \(D\) form will not be converted into the required drug dopamine, and a build up of \(D\)-DOPA can become toxic inside the human body.

\[
\begin{align*}
5, & \text{ R–Thalidomide} \\
6, & \text{ S–Thalidomide}
\end{align*}
\]

The second and far more serious example is in the case of \(R\) and \(S\)–thalidomide, 5 and 6. Thalidomide was discovered in the 1950’s as a powerful sedative and anti–nausea drug that could have great potential in early pregnancy sickness. Unbeknown at the time, one enantiomer was a powerful teratogen, which causes extremely harmful effects on a growing foetus.\(^4\) A *racemic* mixture, a 50% mixture of both enantiomers, was given to the pregnant mothers, and upon the birth of their babies, teratogenic effects were observed affecting the growth of the new born baby’s limbs. After extensive testing it was found that \(R\)–thalidomide was the active and therapeutic drug that showed no teratogenic effects even in high concentrations, whereas \(S\)–thalidomide was shown to be the teratogen and had little sedative and anti–nausea effect.

As observed from these two examples, when designing drugs and utilising natural products, stereo-discrimination is essential to produce enantiomerically pure compounds.
that can be used for human and animal consumption. Due to the inactivity or adverse effects shown by racemic drugs, stringent rules have been imposed over monitoring, regulation and testing. In 2002, 36% of the worldwide pharmacy market consisted of chiral drugs, amounting to >$140 billion.5

1.2 Epoxides

Epoxides are a sub–class of ethers in that they contain the C–O–C unit, but they are configured in a three membered heterocyclic ring system.6 Due to the epoxides heterocyclic structure, which is analogous to cyclopropane and aziridines, it is highly strained, with bond angles at approximately sixty degrees. Therefore epoxides undergo facile ring opening with even the weakest of nucleophiles to generate compounds with stereo- and regio- selective functionality, with the driving force behind the ring opening being the relief of the epoxides highly strained cyclic system.7 Asymmetric epoxidation is an example of asymmetric catalysis that is being developed by multinational research groups.8,9,10,11 The development of enantioselective catalysts enable the generation of one ‘major’ epoxide enantiomer. This, in turn, will enable the highly enantioselective construction of many natural products that contain an epoxide unit.

7, cryptophycin 1: \( R = H \)

8, cryptophycin 52: \( R = Me \)

Cryptophycin 1 and 52 (7 & 8) are two examples of natural products containing an epoxide functionality that exhibits cytotoxic activity against malignant tumours in the human body.12
The gypsy moth is native to parts of the UK and temperate Europe, but accidental introduction to the US in 1879 caused widespread damage and destruction. The female gypsy moth is incapable of flight; she releases a sex pheromone containing an epoxide functionality, (+)-disparlure (9), when ready for mating. The male moth will become attracted to this pheromone, find the female and copulate. The (–)-disparlure enantiomer was found to be totally inactive and shows no activity even at high concentrations. Therefore the active (+)-enantiomer can be used to falsely attract the male gypsy moth in order that numbers can be regulated.

Many natural products contain the epoxide functionality as a single enantiomer, which may be essential for biological activity. The synthesis of chiral epoxides in natural products or as versatile intermediates has shown great potential for economic viability and for future scientific research, especially when incorporated into asymmetric catalytic cycles where the amount of catalyst used remains low and the output of the chiral epoxide is large compared with the quantity of catalyst used.
1.3 Achiral epoxidation of alkenes

The generation of achiral epoxides is often accomplished by the oxidation of alkenes using organic peracids, first discovered in 1909 by Prileshaev. Hydrogen peroxide is the general oxidant used to generate a peracid, the most useful peracids perhaps being peracetic and perbenzoic acids, and substituted derivatives such as \( m \)-chloroperbenzoic acid \((m\text{–CPBA})\) the mechanism of oxygen transfer is shown in Scheme 1.

![Scheme 1](image)

Originally the transition state model of this reaction was thought to be planar (10),\(^{16,17,18,19,20}\) but further research has calculated that the transition state must be a lower energy spiro transition state conformation (11), this transition state model is also known as the ‘butterfly mechanism’ first published by Barlett in 1950. Both transition state models proceed through a concerted mechanism, and therefore the epoxidation is stereospecific.

![10, Planar TS model](image) ![11, Spiro TS model](image)
Alkenes with $\alpha$-situated electron withdrawing groups such as enones can be directly oxidised by a solution of hydrogen peroxide. Weitz and Scheffer first described the use of an alkaline solution of hydrogen peroxide; the alkaline solution deprotonates the hydrogen peroxide, the nucleophilic hydroperoxy anion can then reversibly attack the enones conjugated alkene (Scheme 2). The system can then ring close through nucleophilic attack of the carbon anion at the more electrophilic peroxy–oxygen atom, displacing a hydroxide molecule and generating the epoxide. Due to the long life expectancy of the carbanion, the $\alpha,\beta$ carbon–carbon sigma bond can rotate during the stepwise mechanism and therefore the reaction is not stereospecific.

A second method, used by Richardson and Yao, is achieved by using a bicarbonate-activated peroxide (BAP) at neutral pH. The generation of the electrophilic peracid requires the presence of a carbonate atom, generally sodium hydrogen carbonate or ammonium hydrogen carbonate in a water–based solution. Hydrogen peroxide undergoes nucleophilic attack on the most electrophilic peroxy–oxygen by $\text{HCO}_3^-$ anions, generating peracidic $\text{HCO}_4^-$ anions in solution. The $\text{HCO}_4^-$ percarbonate generates the racemic epoxide through a mechanistic pathway similar to the $m$–CPBA peracidic mechanism observed in Scheme 1, via transition state 12.

12, transition states for percarbonate epoxidation
Phillip Parker; Introduction

Payne, has developed another method of hydrogen peroxide mediated epoxidation.\textsuperscript{22,23} In this system hydrogen peroxide is used in conjunction with a nitrile functionality to generate epoxides in good yield. In the presence of base, hydroperoxy anions nucleophilically attack the nitrile carbon to generate a peroxyimidic acid intermediate (Scheme 3). The peroxyimidic acid is then thought to generate the racemic epoxide through a similar concerted mechanism to that occurring in peracidic epoxidation (Scheme 1). There is however no direct evidence that this mechanism is correct.

\textit{Scheme 3}

1.4 Metal-catalysed asymmetric epoxidation of alkenes

Due to the growing interest in asymmetric epoxidation, many international research groups have developed a range of oxidation catalysts and systems. Several of the most innovative and efficient approaches are reviewed here, with a discussion of their advantages and disadvantages in modern asymmetric catalysis.

1.4.1 The Sharpless catalytic asymmetric epoxidation of allylic alcohols

The Sharpless epoxidation of allylic alcohols was discovered in 1980 by Sharpless and Katsuki.\textsuperscript{24} First, using vanadium and molybdenum metal centred catalysts,\textsuperscript{25} Sharpless found that an allylic alcohol could be substituted for an alkoxide ligand that was already chelated to the metal catalyst. In later work using titanium, the oxidant, \textit{t}-butyl peroxide also displaces an alkoxide ligand, thus generating a titanium complex with both a \textit{t}-butyl peroxide and an allylic alcohol co-ordinated to the central titanium atom. Due to the proximity of the two chelated ligands, the weakly nucleophilic alkene forced nucleophilic attack on to the peroxide generating the epoxide. After further modification, Sharpless discovered the most advanced and efficient catalyst, which was a titanium tetra–isopropoxide-diethyl tartrate (DET) catalyst (13).
The advantages of this methodology were that the procedure is both catalytic and enantioselective. As observed in 13, the chiral Ti(VI) complex exists as a dimer with a C2 plane of symmetry. The predictibility of the stereochemical induction in the epoxide product (Scheme 4) is the main reason that the Sharpless epoxidation has become so important and is so widely used today.

The Sharpless epoxidation has become one of the most important discoveries over the last thirty years, and in 2001 Barry K. Sharpless was presented with the Nobel Prize for Chemistry in acknowledgement of this research.

The dimeric complex is insensitive to other functionality and therefore the process is totally specific to the allylic alcohol moiety, even over other alkenes that may be present. With the selection of the appropriate enantiomer of the catalyst and the correct geometry of the allylic alcohol, generation of the required epoxide enantiomer can be observed in over 90% ee (Scheme 4).
Sharpless epoxidation requires an allylic alcohol, an oxidant; tert-butyl peroxide (TBHP), and the pre–catalyst; Ti(VI) isopropoxide-diethyl tartrate (DET) (Scheme 5). *In–situ* the allylic alcohol becomes chelated to the chiral Ti(VI) metal centre ((Figure 14.1). The most electrophilic TBHP oxygen atom is then nucleophilically attacked by the Ti(VI) chelated t–butyl ester thus, generating the Ti(IV) peroxide ((Figure 14.2).}

[Diagram of the reaction process]

The Ti(IV) is in a bidentate arrangement to both the alkyl alkoxide and the TBHP anion. Due to the close proximity of the two ligands the activated TBHP is then attacked by the weakly nucleophilic alkene at the most electrophilic oxygen ((Figure 14.3). This generates the epoxide preferentially on one of the two enantiotopic faces of the alkene ((Figure 14.4). The Ti(VI) is regenerated by the release of the epoxide, now co–ordinated to the epoxy alkoxide and t–butoxide ((Figure 14.5). The catalytic cycle replaces the epoxy alkoxide with another allylic alcohol ((Figure 14.1), and the t–butoxide with another t–butyl peroxide group ((Figure 14.2). The recycling of the Ti(IV) catalyst has been proven through mechanistic studies (Scheme 6).
\[
\text{Ti(OR)}_4 + 2 \times \text{tartrate} \rightleftharpoons \text{Ti(tartrate)(OR)}_2 + 2 \times \text{ROH}
\]

**Scheme 6**

It was observed that if the alkoxide ligands are replaced by DET–allylic alcohol ligands (Scheme 6),\(^{29}\) the equilibrium lies to the right, towards the DET ester chelated complex. Once the allylic alcohol reacts with the activated THBP, the recycled Ti(IV) releases the epoxy alkoxide and re–chelates to another allylic alcohol.

In previous work Sharpless observed that vanadium and titanium complexes generate intrinsically 1,2–anti products when the allylic alcohol contains functionality at carbon one. Kinetic resolution will occur when using a racemic C1 functionalised allylic alcohol, as one enantiomer will react quicker than its opposite enantiomer.\(^{28}\) Therefore, the Ti(IV) complex will generate the anti–enantiomer faster than the syn-derivative. The slower reacting alkene enantiomer therefore becomes enantiomerically enriched (Scheme 7).
Taking a molecule containing two double bonds that could potentially undergo Sharpless epoxidation, the more nucleophilic of the two reacts more readily (Scheme 8).\textsuperscript{30} Again one enantiomer of the epoxide is generated faster than the other, so this enantiomer is observed in the final mixture as the major product, giving a yield of 35% (out of a possible 50%) and with an enantiomeric excess of greater than 95% ee. The unreacted allylic alcohol is therefore also enantiomerically enriched.

\textit{Scheme 8}
The Sharpless asymmetric epoxidation is a widely used and efficient method for the production of versatile epoxide intermediates, building blocks and the generation of natural products used in organic chemistry.

\[
\text{PMBO} \xrightarrow{\text{O}} \xrightarrow{\text{OH}} \xrightarrow{\text{O}} \text{OH}
\]

Scheme 9

For example, the Sharpless methodology has been used to produce one enantiomer of 3–hydroxypipelicolic acid (Scheme 9).\textsuperscript{31} The \textit{trans}–isomer, 15 generates part of the structure of febrifugine (18), a potent antimalarial agent, and also of (−)–swainsonine (19), which has shown potent and specific \(\alpha\)-\(D\)–mannosidase inhibitory activity. The \textit{cis}–isomer, 16 is a precursor of tetrazomine (17) an anti–tumor antibiotic.
One major limitation of the Sharpless asymmetric epoxidation method is the requirement for the allylic hydroxyl group in order to achieve enantioselective epoxidation. Therefore this method is ineffective in the epoxidation of unfunctionalised alkenes. This limitation has spurred the development of other asymmetric epoxidation methods capable of achieving high enantioselectivity for unfunctionalised alkenes.

1.4.2 Metalloporphyrins as catalysts for asymmetric epoxidation.

In 1983 Groves and Myers first discovered that planar Fe(III) porphyrin complexes are models for the oxidising enzyme cytochrome P450 monooxygenase.\textsuperscript{32,33} Groves and Myers first developed a Fe(III) porphyrin complex catalyst (20) with the ability to oxidise unfunctionalised alkenes.

Many combinations of metal centres and diverse chiral ligands have been screened to try and increase both reactivity and enantiomeric excess. Recently chiral metal porphyrins have been developed that have given moderate to good \textit{ee}; Berkessel’s carbonyl ruthenium(II) metalloporphyrin,\textsuperscript{34} with a novel D4 symmetric ligand (21),\textsuperscript{35,36} Naruta’s iron complex,\textsuperscript{37} with either binaphthalene or a bitetralin–linked porphyrin, and Collman’s iron $\alpha,\alpha,\beta,\beta$–tetrakis(aminophenyl)porphyrin with attached binaphthyl moieties.\textsuperscript{38}
Unfortunately this methodology is substrate-specific, requiring styrene based alkenes producing the corresponding styrene oxides with up to 89% ee. The greatest problem with this epoxidation methodology is the low yielding multistep approach to synthesise the large and complex chiral catalysts.\textsuperscript{39}

1.4.3 Chiral Salen complexes for asymmetric epoxidation.

In 1985, Kochi first devised and reported a manganese(III) Salen complex capable of catalytic epoxidation of unfunctionalised alkenes.\textsuperscript{40,41} Both porphyrins and Salen complexes are initially based on the oxidising enzyme cytochrome P450 mono-oxygenase; it is the oxomanganese(V) cation that is thought to be the active oxidising agent. The major difference between these two types of chiral catalyst is that the oxidised metal porphyrins are planar, whereas Katsuki has shown that the oxidised Salen complexes are based on tetrahedral carbons in close proximity to the metal centre, which give the Salen complexes a folded structure.\textsuperscript{42} This amplifies the asymmetric induction imposed by the chiral catalyst on the generation of the epoxide.

1.4.4 Jacobsen and Katsuki’s chiral Salen complexes.

Jacobsen has developed a multitude of catalysts based on the manganese(III) Salen complexes of chiral Schiff bases. The ligands are derived from chiral 1,2-diamines and substituted salicylaldehydes. Oxidising agents such as periodates and sodium hypochlorite have been utilised to oxidise the Salen pre–catalyst to the oxomanganese(V) active catalyst. Jacobsen’s catalysts have been observed to be particularly effective in the oxidation of \textit{cis}-aryl substituted olefins, for example, catalyst 22 has been shown to produce high ee, up to 98% for certain dimethylchromene derivatives (Scheme 10).\textsuperscript{43,44,45,46,47} However, Jacobsen’s catalysts generate poor selectivity when used in conjunction with \textit{trans}-aryl and aliphatic alkenes.
Katsuki has also reported chiral Mn(III) catalysts, developing catalyst 23. This method uses chiral residues attached at an aromatic carbon ortho to a phenolic group.

Katsuki’s catalyst contains the standard asymmetric centres at the 1’ and 2’ positions, but Katsuki’s catalyst, 23, differs from Jacobsen’s as it also contains axial chirality in the form of enantiomerically pure binaphthyl groups incorporated into 3,3’ positions. Katsuki’s system exhibits similar enantioselectivities to the Jacobsen catalyst for cis–aryl alkenes, greater than 99% ee for certain dimethylchromene derivatives (Scheme 11). However greater enantioselectivities are observed when oxidising trans–alkenes.

The enantioselectivity in epoxidation is believed to be induced by a chiral Salen catalyst through a side on approach of the alkene to the oxomanganese(V) intermediate. It is known that asymmetric centres at carbon 1’ and 2’ induces higher enantioselectivity in epoxidation of cis–aryl alkenes.
The 3,3’ axial symmetry (R₃/ R₃’ groups) directs the orientation of the approach of the substrate alkene towards the oxo–Mn(V) bond (solid arrow, figure 24). The 3,3’ functionality inhibits approach from the more sterically hindered face (dashed arrow). Therefore, these interactions enforce enantiofacial selection of the oxygen transfer and explain the raised enantioselectivity of the Katsuki Salen complex, especially for trans-alkenes.

One major disadvantage with Salen Mn(III) epoxidation is the lack of retention of the alkene configuration in the epoxidation of some substrates. This is especially the case when attempting to oxidise aryl–substituted acyclic cis–alkenes. Epoxidation of these acyclic alkenes does not occur with retention of configuration.
The cause of this (Scheme 12) is postulated to be a step–wise radical mechanism in which bond rotation of the radical intermediate causes the scrambling of the cis–geometry to yield the trans–epoxide. This problem was ‘modified’ by the addition of quaternary cinchona alkaloid-derived salts to the reaction mixture, to give trans–epoxides in up to 90% ee.

![Mn-Salen complex diagram](image)

**25, Conformationally reversed Salen complex**

More recently, Katsuki has developed a conformationally reversed Salen complex (25), with an attached carboxylate group on the ethylenediamine moiety.\(^{55}\)

In a standard Salen complex, due to the tetrahedral geometry of carbon 1, which would hold the asymmetric functionality, this group is forced pseudoequatorial (Scheme 13), making the Salen complex adopt a folded rather than planar conformation confining the olefin to only approach from over the 1’, 2’ positions. It is this conformation that controls the asymmetric induction of the epoxidation in all Salen complexes.

![Scheme 13 diagram](image)

**Scheme 13, Pseudoequatorial and pseudoaxial conformations of Mn-Salen complexes**
In the conformationally reversed Salen complex, the catalysts conformation forces the carboxylate group, at carbon 1’, pseudoaxial (Scheme 13). Due to the exchange from pseudoequatorial to pseudoaxial conformation, the carboxylate group can then stabilise the oxo–Mn(V) active catalyst. This change in conformation now confines olefin approach from over the 3 and 3’ positions, thus inducing the opposite enantiocntrol. For example, dimethylchromene derivatives are oxidised with up to >99% ee.

The Jacobsen/Katsuki Salen-mediated asymmetric epoxidation has proven to be one of the most successful methods for epoxidation of cis–aryl alkenes with high enantiomeric excess. Unfortunately Salen catalysed reactions suffer from two fundamental problems. Firstly a loss of stereospecificity through a radical intermediate is observed. Secondly, and most importantly, Salen complexes are only successful in the oxidation of aryl alkenes, meaning that Salen complex methodology is of limited use.

1.5 Metal-free catalytic asymmetric epoxidation.

1.5.1 Julia–Colonna epoxidation of α,β–unsaturated ketones.

In 1980 Julia and Colonna demonstrated that high enantioselectivities, up to 97%, could be achieved in epoxidation of an α,β–unsaturated ketone such as chalcone (Scheme 14).

Julia developed a triphasic oxidative system containing poly–L–alanine, toluene, and aqueous alkaline hydrogen peroxide as the oxidant. Unfortunately the Julia methodology suffers from extended reaction times of up to 24 hours and low substrate scope.

Scheme 14

Roberts has further investigated the Julia–Colonna epoxidation. Roberts has produced an
improved biphasic system that reduces reaction times to approximately thirty minutes,\textsuperscript{58,59} increasing the enone substrate range to include some unreactive, \(\alpha\)-substituted and \(cis\) substituted aryl, heteroaryl and alkenyl enones, but most importantly maintaining the enantioselectivity (97\% \(ee\) for chalcone). Under the new biphasic conditions the reaction is performed in a non–aqueous solvent, such as THF, using a water–free source of hydrogen peroxide; the readily available urea–hydrogen peroxide popularised by Heaney was the oxidant of choice.\textsuperscript{60} DBU is used as a non–nucleophilic base.\textsuperscript{61}

In 1976 Wynberg introduced the idea of phase transfer catalysis (PTC) for epoxidation, an alternative method to facilitate the production of an epoxide from an \(\alpha,\beta\)–unsaturated ketone with high enantiocontrol. Wynberg used a quinine-derived quaternary ammonium salt (26) as the chiral phase transfer catalyst in the presence of alkaline hydrogen peroxide and a stoichiometric oxidant, giving up to 55\% enantiocontrol when using chalcone as the test substrate.\textsuperscript{62,63,64,65,66,67}

\[
\begin{align*}
\text{Scheme 15}
\end{align*}
\]
Further work by other research groups has proven that the quinine-derived quaternary ammonium salts, such as 26–28, generate high ee when investigating enantioselective α,β–unsaturated ketone epoxidation. Lygo has generated modifications of catalyst 27 giving enantioselectivities of 71–90%,68,69,70 and Arai has identified catalyst 28; by exchanging the halogen group on the benzyl functionality up to 92% enantiocontrol has been achieved.71,72 Lygo and Maruoka have also produced C2–symmetric catalysts 29 and 30, containing BINAP and a biphenyl azepinium ring functionalities, both giving up to 97% enantioselectivity.73,74,75

1.5.2 Dioxirane mediated asymmetric epoxidation.

1.5.2.1 General overview

Dioxirane–mediated asymmetric epoxidation has emerged as one of the most effective methods for producing enantiomerically enriched epoxides over the past twenty years. The general method for production of a dioxirane is by the use of a ketone and a stoichiometric oxidant, generally Oxone®, in either a monophasic (CH₃CN/H₂O) or a biphasic (CH₂Cl₂/H₂O) system at neutral pH (7–8) (Scheme 16). The composition of Oxone® is 2KHSO₅.KHSO₄.K₂SO₄, the active component being potassium monopersulfate (KHSO₅, potassium peroxomonosulfate). The use of Oxone® has increased rapidly due to good stability, simple handling, the non-toxic nature, the versatility of the reagent and the low cost.

\[ \text{Scheme 16, dioxirane mediated epoxidation} \]
In the early 1980’s, research groups lead by Curci and Marples both described the generation of stoichiometric dioxiraines from chiral ketones (31 – 35). 76,77,78 They were used as pre–catalysts for dioxirane-mediated asymmetric epoxidation of alkenes, affording their respective epoxides in up to 20% ee.

1.5.2.2 Shi’s chiral–fructose derived ketone catalysts.

In 1990 Shi designed a fructose–based ketone catalyst, 36, that displayed remarkably desirable features for asymmetric epoxidation, affording up to 95% ee in the epoxidation of trans–stilbene (Scheme 17).

The fructose ketone catalyst (36), is oxidised to the dioxirane with a stoichiometric oxidant such as Oxone® (Scheme 18). 79

The electrophilic dioxirane undergoes nucleophilic attack from the alkene, which generates the epoxide. Trans– and tri-substituted alkenes give from 80% to 95% ee. The desirable features of the fructose catalyst are the close spacing of the stereogenic centre(s) and the reacting centre(s), resulting in efficient chemical communication
between the dioxirane and the substrate. The fused rings on the α-carbons reduce epimerisation of the stereogenic centres. Electron-withdrawing groups may be added to the ketone to activate the carbonyl functionality.\textsuperscript{80,81}

\begin{center}
\textbf{Scheme 18, Shi’s catalytic dioxarine epoxidation}
\end{center}

Unfortunately, Shi’s catalyst undergoes decomposition through Baeyer–Villiger oxidation,\textsuperscript{82,83} and so the amount of catalyst is typically 30 mol\% (Scheme 18). This problem was eased by raising the pH of the reaction from neutral, pH 7/8, to alkaline, > pH 10 with the addition of potassium carbonate. The resulting epoxides were gained with increased \textit{ee} ranging from 91\% to 97\% and are stable under basic conditions (Scheme 17).

Another result of the raised pH was that the nucleophilicity of the Oxone® was also increased. Not only does this help suppress the Baeyer–Villiger side reaction therefore increasing the yields of selected epoxides to 95\%, but increased the rate of reaction therefore reducing the amount of catalyst required to 20 mmol\%.

The synthetic utility of this methodology\textsuperscript{84,85} was widely explored by the asymmetric epoxidation of various hydroxyalkenes (90–94\% ee), enol ethers and enol esters (80–
91% ee), enynes (90–97% ee), vinylsilanes (84–94% ee), 
\( cis \)-alkenes (84–97% ee), terminal alkenes (30–94% ee), and mono–epoxidation of conjugated dienes (90–97% ee). The epoxidation of conjugated dienes has also been shown to be highly enantioselective. Kinetic resolution of racemic 1,3-disubstituted cyclohexenes and racemic allylic substituted cyclic olefins has also been completed.  

\[ 1.5.2.2.1 \] Transition States for ketone catalysts

There are two possible transition state models (transition state–models) to describe how the alkene interacts with the dioxirane, the spiro and planar transition state models (Scheme 19).  

![Scheme 19, Spiro and Planar transition state models](image)

A transition state model is invaluable for predicting the stereochemical outcome of the epoxidation reaction. The large, bulky functional groups on both the alkene and the dioxirane directly determine the angle and orientation of the approach of the substrate to the catalyst, therefore determining the regio- and stereochemistry of the epoxide produced. Scheme 19 shows the two major transition state models for Shi’s fructose catalyst, spiro and planar. The alkene approaches the dioxirane, placing the bulky R groups away from the dioxiranes ketal moieties, therefore reducing repulsive steric and electronic interactions.

The spiro transision state model is favoured over the planar model, due to the overlap and therefore stabilising interaction between the reacting lone pair of the oxygen and the the \( \pi^* \) orbital of the alkene (stereoelectronic origin). The oxygen lone pair and the \( \pi^* \) orbital do not overlap in the planar transision state model, so there is less stabilisation.
Shi showed that the asymmetric epoxidation of \textit{trans} and \textit{tri}-substituted alkenes was efficiently completed with the fructose-derived ketone catalyst. The stereochemistry was predictable using a simple model. Unfortunately \textit{cis} and terminal alkenes were a problem as the largest group(s) on the alkene could point away from the dioxirane, resulting in poor selectivity as the alkene could flip 180 degrees (Scheme 20).

\begin{center}
\textit{Scheme 20}
\end{center}

Shi has also reported alkaline hydrogen peroxide-mediated asymmetric epoxidation in the presence of nitriles. The peroxyimidic acid reported by Payne is postulated to be the active oxidant in the dioxirane generation of the fructose catalyst (Scheme 21). High yields and enantioselectivities under these reaction conditions with up to 95\% \textit{ee} for 1–phenylcyclohexene oxide have been reported.

\begin{center}
\textit{Scheme 21, hydrogen peroxide-mediated dioxirane epoxidation}
\end{center}
Unfortunately the original fructose catalyst is ineffective for electron-deficient and \( \alpha,\beta \)-unsaturated alkenes due to the decomposition through the Baeyer–Villiger reaction. Shi designed two further catalysts. From wide screening, Shi observed that (–)-quinic acid-derived catalyst 37 showed increased enantiocontrol, up to 94\% ee, and increased rates of reaction, up to 80\%, over the original fructose catalyst (36).\(^{90}\)

**Scheme 22**  
**Catalyst 37, 94\% ee**

With the success resulting from this additional acetate group, Shi then adapted the original fructose catalyst, exchanging the lower 2,3- ketals for two acetate moieties, generating catalyst 38.\(^{84}\) The electron withdrawing ability of the acetate groups again inhibited the Baeyer–Villiger reaction. The enantiocontrol was increased for trans and tri-substituted alkenes as well as for \( \alpha,\beta \)-unsaturated alkenes (82 – 98\% ee). The rate of reaction was also greatly increased.\(^{91}\)

**Scheme 23**  
**Catalyst 38, > 95\% ee**

Shi designed a nitrogen analogue of the fructose catalyst,\(^{82,85}\) the rationale being that the nitrogen substitution could impart enantiocontrol in the epoxidation of cis and terminal alkenes. The nitrogen functionality was added to the fructose ketone by the Amadori rearrangement,\(^{82,85,929394}\) and the highest enantiocontrol was observed when a \( N \)–Boc

**Phillip Parker; Introduction**
group was incorporated in the catalyst (39). The enantioselectivity for \textit{trans} alkenes was observed to be lower when using 39,\textsuperscript{82,85} but for \textit{cis} and terminal alkenes the nitrogen analogue gave up to 94% and 85% \textit{ee} respectively (Scheme 24). An additional feature of the nitrogen analogue is that it retards the Baeyer–Villiger reaction to a higher degree than the original fructose catalyst (36).

\begin{center}
\textbf{Scheme 24} \hspace{1cm} \textbf{Catalyst 39, 91\% ee}
\end{center}

Shi has suggested that there may be an attraction between the R\(\pi\) functionality of the approaching alkene and the oxazolidinone of the ketone catalyst (41).\textsuperscript{16,95} As a result of this, alkene groups containing R\(\pi\) functionality (41) may be significantly differentiated from those without (40), leading to increased enantioselectivity. Shi further demonstrated that catalysts containing \textit{N}-aryl substitution (R\(_1\)) strengthen the attractive interaction through conjugative electron withdrawal from the oxazolidinone functionality. It is postulated that the approaching alkene containing \(\pi\) functionality and the electron poor oxazolidinone undergo an electronic field effect i.e. a through-space electrostatic interaction.\textsuperscript{96,97,98} The exact nature of this attractive interaction between the R\(\pi\) functionality and the oxazolidinone is not clear at present.\textsuperscript{16,99}

\[ \text{R}_1 = \text{aryl or alkyl. R}_2 = \text{alkyl. R}_{\pi} = \text{aryl or conjugated system.} \]

\begin{center}
\textbf{40} \hspace{1cm} \textbf{41}
\end{center}

\textit{Spiro} \hspace{1cm} \textit{Spiro (favoured)}
Structural evidence of most effective catalysts revealed that the nitrogen substituent (R₂) points firmly away from the dioxirane, therefore proving that it (R₂) could not influence the alkene sterically, only electronic factors may be important.¹⁷

The same rationale was applied to terminal and geminal alkenes.¹⁷,⁸²,⁸⁵ The ketone catalysts oxazolidinone functionality may differentiate, using an electronic field interaction, between the approaching alkenes functional groups; those in which contain Rπ functionality (42 & 43) and those in which the Rπ functionality is absent. This differentiation imparts increased enantiocontrol onto the selected alkene.

\[
\begin{align*}
R₁ &= \text{aryl or alkyl. } R₂ = \text{alkyl. } Rπ = \text{aryl or conjugated system.}
\end{align*}
\]

Due to the need for π character the Catalyst 39 performs poorly with non-aryl alkenes.

Shi has reported a skeletal alteration of the pyranose catalyst 39 by generating a catalyst with carbocyclic skeleton, catalyst 44, which has been shown to give enantioselectivities of 89 – 93%, unfortunately the difficult and lengthy synthesis of 44 paired with the requirement of an aryl alkene makes it an unattractive tool for catalysis.
Most recently Shi has formed more efficient derivatives of pyranose catalyst 39. Catalysts 45 and 46 are prepared from $D$–glucose and have been used to impart enantiocontrol over styrene (80 – 92% ee), $cis$ alkenes (81 – 98% ee), conjugated $cis$-dienes (76 – 94% ee) and conjugated $cis$–enynes (80 – 97% ee).

![Chemical structures](image)

Other research groups such as Shing, Adam and Zhao have all generated sugar based dioxirane catalysts. $^{100,101,102}$ These oxidations are believed to proceed through similar transition states to Shi’s fructose catalyst, however they have not provided epoxides with high enantioselectivity.

1.5.2.3 **Dan Yang: C2 symmetric dioxirane catalysts**

Yang’s most efficient C2 catalyst (47) has been developed from 1,1′–binaphthyl–2,2′ dicarboxylic acid. $^{103}$ In these C2 symmetric molecules the binaphthalene units are used as the chiral control element keeping the C2 symmetric ketone rigid. The catalyst also contains two large ketal groups at positions 3 and 3′. These groups have two responsibilities, first to help facilitate activation of the carbonyl functionality, through electron withdrawal, enabling the formation of the dioxirane catalyst. $^{104,105}$ Secondly, and most importantly, they act as steric control elements. The ketals are the closest functionalities in space to the dioxirane when oxygen transfer occurs, and they help to direct the approach of the alkene.
High enantioselectivities were obtained for trans-disubstituted and tri-substituted alkenes, the best substrate being trans-4,4’-diphenylstilbene, giving 95% ee.

1.5.2.4 Armstrong’s α–functionalised dioxiraine

In 1998 Armstrong reported the electronic activation of a catalyst capable of asymmetric alkene epoxidation. Armstrong focused on α–functionalised ketones. As previous research within the group had shown that α–Amido ketones were unsuccessful as the carbon atom alpha to both the amine and ketone becomes highly electropositive due to extensive electron withdrawal. The α-carbon is therefore prone to Baeyer–Villiger decomposition. β–Amido ketones are not prone to the Baeyer–Villiger reaction and thus favoured as dioxiraine catalysts. Armstrong was able to generate well-defined chiral catalysts based on tropinone derivatives (48).
Fluorine, a very strong electron-withdrawing group, was placed \( \alpha \) to the ketone, in order to activate the ketone by withdrawal of electron density. The equatorial fluoro compounds were the most reactive as well as being the most stable to the Baeyer–Villiger reaction.\(^{107,108}\) These \( \alpha \)-fluoroketone catalysts oxidised trisubstituted aryl alkenes with up to 83\% ee.

The enantioselectivity of the epoxide generation has been explained by transition state–models.\(^{109}\) The \( \alpha \)-fluorine has a dipole interaction with the approaching alkene, and this directs the alkene to one enantiotopic face, generating an enantioselective epoxidation.

### 1.5.2.5 Denmark’s \( \alpha \)-functionalised chiral dioxiranes

Denmark has devised, among other chiral ketone catalysts, a bis-fluoro dioxirane catalyst with the ability to catalyse asymmetric epoxidation.\(^{110,111,112}\) Denmark has shown that good to excellent enantioselectivities for \textit{trans}–alkenes can be achieved when using catalyst 49. However, catalyst loadings are high (30 mol\%).

![Denmark's \( \alpha \)-fluoro chiral ketone](image)

\(49, \text{Denmark's} \ \alpha\)-\textit{fluoro} chiral ketone

Denmark postulated a spiro transition state model for this biaryl chiral dioxirane. Due to the catalysts C2 symmetry, the activated dioxirane oxygen atoms become homotopic,\(^{112}\) the alkene may then approach the biaryl skeleton through either route a, or route b (Scheme 26).
The approach through route b is disfavoured due to the proximity of the methyl substituents. Route a does not suffer from this steric interaction and therefore becomes the favoured spiro transition state. Denmark has also postulated that catalyst 49 may impart higher levels of enantiocontrol over alkenes with aryl functionality, this may be due to an electronic, π-π stacking interaction between the catalyst, and the alkenes aryl substituents.

1.5.3 Iminium/oxaziridinium salt mediated asymmetric epoxidation

1.5.3.1 Initial observations by Lusinchi

In 1976 Lusinchi first reported the use of oxaziridinium salts in asymmetric epoxidation. He observed that an unstable oxaziridinium salt could be prepared by peracid oxidation of an achiral steroidal imine with Oxone®, followed by quaternisation using methyl fluorosulfonate (Scheme 27).113,114,115

The oxaziridinium salt so generated contains a highly electrophilic oxygen atom. Lusinchi postulated that this highly strained heterocycle could then transfer the oxygen to an alkene.116
Lusinchi proved his postulate by deriving an oxaziridinium salt from dihydroisoquinoline.\textsuperscript{116,117,118,119} The imine was oxidised to the oxaziridine with a peracid and then quaternised with methyl fluorosulfonate. This oxaziridinium salt transferred the electrophilic oxygen to several simple nucleophilic alkenes in good yield.

Following this breakthrough, Lusinchi prepared the first enantiomerically pure oxaziridinium salt. This was achieved by quaternisation of an oxaziridine, derived from (1S,2R)-(+)-norephedrine, producing the oxaziridinium salt, 50 (Scheme 28).\textsuperscript{120}
Reaganets and conditions; (a) PhCHO, NaBH₄, (b) CF₃COOH, H₂SO₄, (c) NaOCl, NaOMe, (d) MCPBA, MeOH, (e) Me₃O⁺BF₄⁻, (f) Me₃O⁺BF₄⁻, MeOH, (g) NaHCO₃, p-nitrobenzoic acid

Scheme 28

Lusinchi used this enantiomerically pure oxaziridinium salt (50) in stoichiometric amounts to oxidise simple alkenes to their corresponding epoxides, for example trans-stilbene gave up to 33% ee. Lusinchi reported that a side product of the reaction was the iminium salt. He described that upon oxygen transfer from the oxaziridinium salt to the substrate alkene, the iminium salt catalyst was generated. If an oxidant is then added to this iminium ion, the oxaziridinium ion is regenerated and, capable of oxygen transfer to the alkene.

Lusinchi developed this approach with the addition of a catalytic amount (20 mol%) of the norephedrine iminium salt (50). He observed that trans-stilbene was again generated with 33% ee.

Lusinchi has shown that oxaziridinium salts are wide-spectrum oxygen transfer reagents. They are capable of transferring oxygen to other nucleophilic substrates such as; sulfides, to generate sulphoxides; amines, to generate nitrones; and imines, to generate oxaziridines.
Bohé, a student of Lusinchi, has since shown that dihydroisoquinolinium salt catalysts can undergo loss of active oxygen from the oxaziridinium salt.\textsuperscript{123} This occurs with irreversible base catalysed isomerisation of the oxaziridinium salt containing protons $\alpha$ to the nitrogen atom. This isomerisation causes a breakdown in the catalytic cycle.

Bohé has therefore developed a more stable achiral 3,3-disubstituted dihydroisoquinolinium catalyst (Scheme 29). This catalyst has displayed increased stability in comparison to the unsubstituted dihydroisoquinolinium catalyst, as it cannot undergo base catalysed isomerisation, due to there being no $\alpha$–protons adjacent to the nitrogen atom.\textsuperscript{123,124}
1.5.3.2 A C2–symmetric binaphthalene based iminium salt.

Aggarwal and Wang have reported an iminium salt catalyst that is based on a C2 symmetric binaphthalene functionality.\textsuperscript{125,126,127} Catalyst 51 is thought to undergo oxidation with Oxone® to produce preferentially one diastereoisomer of the active oxaziridinium catalyst. This helps to induce enantiocontrol in the epoxidation by the exclusion of the competing oxygen transfer transition states on the more hindered face of the oxaziridinium salt.\textsuperscript{128}

This binaphthyl-based iminium catalyst afforded 1–phenylcyclohexene oxide inducing 71\% ee. All other alkenes tested gave lower ee.

1.5.3.3 Acyclic/exocyclic iminium salt catalysed asymmetric epoxidation

Armstrong has produced a range of acyclic iminium salt catalysts that transfer oxygen from the oxaziridinium unit to the nucleophilic alkene. These exocyclic iminium salts (52) were produced by the condensation of trimethylsilylpyrrolidine with aromatic aldehydes in the presence of trimethylsilyl triflate.\textsuperscript{129}
Armstrong observed that only aromatic iminium salt derivatives with a substituted electron–withdrawing group such as a chlorine or trifluoromethyl group would catalyse the reaction. Catalyst 52 afforded 100% conversion of \textit{trans}–stilbene to the corresponding epoxide.\textsuperscript{130}

Armstrong attempted to derive a range of exocyclic iminium salt catalysts comprising of binaphthyl units, methoxy substituted naphthyl groups, and chiral pyrrolidines. The only positive results were gained with the pyrrolidine catalysts, but these catalysts gave low enantioselectivities.

Komatsu has produced a set of aliphatic ketiminium salts bearing an exocyclic iminium unit. They are easily prepared by the condensation of cyclic amines with cyclic ketones in the presence of HBF\textsubscript{4}.\textsuperscript{131}

It was found that 53 gave the best conversion to the epoxide. A chiral version of this ketiminium salt, 54, was produced, which gave 39\% ee and 70\% conversion when using cinnamyl alcohol as the substrate.
More recently, Yang discovered that the condensation of an amine (55) with a suitable ketone (56) under acidic conditions generated the iminium salt *in situ*; this iminium salt then efficiently catalysed the epoxidation of trans-α-methylstilbene, imparting 59% ee (Scheme 31). Further research showed that some amines could individually mediate the epoxidation of alkenes by oxygen transfer *via* a peracid intermediate.\(^{132}\)

![Scheme 31, in situ generation of the iminium salt](image)

### 1.5.3.4 Intramolecular epoxidation of unsaturated oxaziridines

Armstrong has also reported his findings on an enantioselective intramolecular asymmetric epoxidation.\(^{133}\) An imine was generated from the condensation of a primary amine and an unsaturated aldehyde. The imine was converted to the oxaziridine salt as a pair of separable diastereoisomers (Scheme 32).
Both oxaziridines were converted into oxaziridinium salts by methylation of the nitrogen with methyl trifluoromethanesulfonate. In the presence of these oxaziridinium salts, the attached alkene underwent intramolecular asymmetric epoxidation with 84 – 98% ee depending on the identity of R₁, R₂ and R₃.

Armstrong has suggested that the high stereoselectivity occurs through each of the two diastereoisomeric oxaziridinium salts progressing through one of two different transition states. The planar transition state model (58) generates the opposite stereochemistry to that of the parent oxaziridine. For example, the planar transition state of the (2R, 3R) gives the pro–S conformation. The spiro transition state model (57), however, retains the stereochemistry from the oxaziridine used; the (2R, 3R) oxaziridine gives the pro–R conformation.
Experiment shows that both diastereoisomers of the oxaziridinium species give results consistent with the spiro transition state model (57). Unfortunately there is a loss of selectivity when the chain length exceeds three atoms between the aldehyde and alkene.

1.5.3.5 Page’s chiral iminium salt catalysts

1.5.3.5.1 Dihydroisoquinolinium salt catalysts

Initially based around the findings of Lusinchi and Bohé the Page group produced their own dihydroisoquinolinium salt catalysts with important variations. They introduced a chiral exocyclic nitrogen substituent through cyclo-condensations of primary amines with 2–(2–bromoethyl)-benzaldehyde and subsequent counter ion exchange with tetraphenylborate to generate the crystalline iminium salts (59). The rationale was that the close proximity of the exocyclic asymmetric centre to the site of oxygen transfer would increase the enantiocontrol induced in the epoxidation of alkenes.136
59, Page's isoquinolinium salt catalyst

A range of primary amines were cyclo-condensed with the bromoaldehyde and tested for their enantioselectivity in the epoxidation of simple alkenes.

Figure 60

The general method of epoxidation used Oxone® (2 equiv.) as the stoichiometric oxidant in MeCN/H₂O (1:1), Na₂CO₃ (4 equiv.) as base and the iminium salt catalyst (10 mol%). Initial observations showed that one catalyst gave higher enantioselectivity than all others; this was the N–isopinocampheyl derivative (61) that gave 40% enantioselectivity at 0 ºC for the epoxidation of 1–phenylcyclohexene.

61, N–isopinocampheyl iminium salt catalyst
The mechanism of oxidation is hypothesised to occur through nucleophilic attack of the persulphate oxidant (KHSO$_5$) on the electrophilic iminium carbon atom, forming a pair of persulphate diastereoisomers as the nucleophile can attack at either the $Re$ or $Si$ face of the iminium bond.$^{137}$

It is currently suspected that the rate-determining step is the subsequent nitrogen lone pair attack on to the most electrophilic oxygen, displacing a sulphate-leaving group to give the two corresponding diastereoisomeric oxaziridinium salts. The oxygen transfer by these diastereoisomeric oxaziridinium salts onto the prochiral faces of the alkene substrate may occur with varying degrees of enantiocontrol through a spiro transition state model (Scheme 33).$^{138}$

Scheme 33

1.5.3.5.2 Reaction parameters

A review of the reaction parameters was completed in order to optimise the reaction conditions with respect to the enantioselectivity of the oxidation process. The isopinocampheylamine derivative was chosen as the model catalyst for the optimisation of the parameters that were thought to influence the enantioselectivity of the process.$^{139}$

In addition to the original tetraphenylborate anion, the corresponding bromide, tetrafluoroborate, hexafluorophosphate, perchlorate and periodate salts were also prepared. All of the salts were tested in the asymmetric catalytic epoxidation of 1–phenylcyclohexene. The periodate and bromide salts produced enantioselectivities (35%
and 40% respectively) comparable to those obtained with the tetraphenylborate catalyst (40\% ee), while the fluoride containing counter–ions afforded lower ee (28\%), as did the perchlorate salt (20\% ee). All of the salts produced the same enantiomer of the epoxide product \((R,R)\) as the major component, and all of the reactions were complete within the same time scale, ~ 45 minutes.

As previously indicated, the standard oxidation solvent used was acetonitrile/water (1:1 or 2:1). Initial observations suggested that increasing the water concentration in acetonitrile also increased the rate of oxidation. Presumably a result of increasing Oxone® solubilisation with increasing water concentration, such that the rate of nucleophilic attack by persulphate on the iminium species is increased, leading to a concentration effect coupled with better solvation of the departing sulfate ion. Yang has more recently published evidence that in the presence of a bicarbonate salt the rate of reaction can be increased, if the amount of water is reduced to 10% in acetonitrile.

Reducing the amount of Oxone® and base by a factor of two (i.e. using one equivalent of Oxone® and two equivalents of sodium carbonate), resulted in incomplete conversion after one hour in the improved (2:1) solvent system. This may result from competitive decomposition of Oxone® under the basic conditions, and hence, in a faster reaction, more of the unstable oxidant is consumed in the desired oxygen transfer process. The effect is more pronounced when small amounts of catalysts are used. It was also observed that there was no significant change in enantiocontrol when the reaction temperature was varied from –10 °C to 30 °C for varying co-solvent ratios.

Increasing the water content of the reaction solvent system gives a considerable rate change without change in enantioselectivity. This suggests that the rate-determining step does not involve oxygen transfer to the substrate, i.e. that the subsequent enantioselective oxygen transfer to alkene is not the rate-determining step under these conditions (Scheme 33).

Also investigated was the potential correlation of reaction rates and extent of asymmetric induction with the polarity of the co–solvent. The co–solvents used were selected so that they differed significantly in dielectric constant (indicated by the values in brackets):
dichloromethane (8.9), trifluoroethanol (26.7), acetonitrile (37.5), water (78.4), formamide (111).

![Scheme 34](image)

The epoxidation of 1-phenylcyclohexene with the isopinocampheyl catalyst (61) was performed in a 1:1 ratio of co-solvents. In order also to examine the counter-ion effect (Scheme 34), the catalyst was tested both as its perchlorate and tetraphenylborate salts (20 and 40% ee respectively, in acetonitrile). The perchlorate and tetraphenylborate salts mediate the quantitative epoxidation of 1-phenylcyclohexene in trifluoroethanol within 30 minutes and 26% ee. There was no reaction in formamide for either salt, suggesting that the iminium species are too well stabilised, and the possibility of an irreversible reaction with formamide is also possible. In dichloromethane, enantioselectivity mediated by the perchlorate salt increased to 33% but only 50% conversion after three hours whereas the tetraphenylborate gave no oxygen transfer. The difference in reactivity for the counter-ions in dichloromethane/water reflects the poor miscibility of the two solvents, which must severely limit the availability of the inorganic oxidant in the organic phase.

For the isopinocampheyl tetraphenylborate salt, catalyst loading with respect to enantiocontrol is shown in Figure 62. Using a fixed concentration of 1-phenylcyclohexene as substrate, the graph shows that the enantioselectivity remains within experimental error as the catalyst loading decreases from 5 mol% to 1 mol%. Lower catalyst loading, down to 0.1 mol%, results with complete conversion of the substrate alkene to the desired epoxide but with a reduction in the enantioselectivity. Later work has shown that other catalysts appear to suffer less in this regard.
Page hypothesised that the presence of a primary or secondary hydroxyl group may improve enantioselectivity. Therefore a range of iminium salt catalysts was prepared from chiral amino alcohols, but unfortunately both poor reactivity and enantioselectivity were observed.  

Page then introduced a substituted dioxane functionality, using (1S, 2S)-2–amino–1–phenylpropane–1,3-diol, which was protected as the acetonide. This gave a dioxane unit with a primary amine that would undergo cyclo-condensation with the bromoaldehyde. This \( N \)-aminodioxane-functionalised iminium salt catalyst (63) was employed in the epoxidation of alkenes, and it induced similar enantiocontrol to the \( N \)-isopinocampheyl derivative, for example giving 40% \( ee \) at 0 °C when oxidising 1–phenylcyclohexene (Scheme 35).
1.5.3.5.4 Electronic control of dioxane sub-units

The success of this N-aminodioxane catalyst is thought to stem from the high conformational rigidity of the six-membered dioxane ring and also the syn relationship between the nitrogen heterocycle and the phenyl moiety. NMR spectroscopy and single crystal X-ray analysis suggest that the dioxane ring retains its chair conformation by placing the nitrogen heterocycle axial and the equally large phenyl ring equatorial (64). This thermodynamically favourable conformation reduces the 1,3-diaxial interactions and allows electronic interactions between the oxygen lone pairs and the electron poor carbon iminium atom (65).\(^\text{138}\)

Therefore the thermodynamic conformation leading to the equatorial positioning of the phenyl ring may then help inhibit approach toward one face of the iminium unit by either the Oxone® oxidant or the approaching olefin. One diastereoisomeric oxaziridinium salt may therefore be favoured (66) over the other and in turn generating epoxides with increased ee.
Of the two generalised transition state models, the spiro transition state is the accepted model with in iminium salt catalysed asymmetric epoxidation. Due to the postulated conformer \( 64 \), the presence of the phenyl group may hinder the attack of the oxidant at the \( si \) face therefore generating the minor oxaziridinium diastereoisomer (Scheme 36). The oxidant attack at the \( re \) face is therefore favoured, thus generating the major oxaziridinium diastereoisomer, which through a spiro transition state undergoes oxygen transfer to the alkene yielding the epoxide with high enantiocontrol.

![Scheme 36](image)

**1.5.3.5.5 Biphenyl azepinium salts**

The Page group have also exchanged the dihydroisoquinolinium backbone (63) for a biphenyl structure fused into an azepinium salt (67) in the hope of increased enantioselectivity. \(^{11}\)

![67, azepinium salt catalyst](image)
Preparation of this catalyst proceeded through ring closure of 2,2’–biphenyldimethanol with HBr to give the dibenzooxepine. Treatment with bromine generated the bromoaldehyde, which can then be condensed with the primary aminodioxane. Addition of NaBPh₄ gave the desired iminium salt catalyst (67). This azepinium salt catalyst generated 60% ee and 100% conversion for 1-phenylcyclohexene in under 10 minutes (5 mol%), showing that the biphenyl substructure increased both enantioselectivity and rate of reaction over previous catalysts (40% ee for both catalyst 61 and Catalyst 63).

It was observed that the Oxone® system would only work if the solvent system in use contained a high percentage of water. Oxone® has the highest solubility in water over any organic solvent. Due to the quantity of Oxone® used (2 mmol) it will only dissolve in a considerable volume of water (~ 4.25ml), this is equal to the amount of the co–solvent (MeCN) required, making the ratio of solvents 1:1. This has a limiting effect on the range of temperatures at which the reaction can be carried out. The highest reaction temperature is defined by Oxone® itself as it starts to decompose at approximately 30 °C. The lowest temperature is defined by the solvent system; the use of a 1:1 (MeCN:H₂O) co–solvent system allows the temperature to be reduced to –8 °C before the aqueous phase freezes. An opportunity to enhance the enantioselectivity of the process could be provided if the reaction could be completed at lower temperatures.

Therefore the Page group investigated other oxidants with the idea of designing a non–aqueous epoxidation system. They found that tetraphenylphosphonium monoperoxysulfate (TPPP, 68) gave the highest enantioselectivity of all oxidants tested. Most importantly, it is completely soluble in organic media, gave no background epoxidation and at –40 °C gave good enantioselectivity in the epoxidation of 1–phenylcyclohexene, attaining 67% ee
A temperature study was undertaken, as lower temperature could now be attained without freezing of the reaction medium. First it was found that MeCN gave higher ee than methylene chloride when used as the reaction solvent. Secondly, and most importantly, as the temperature of the reaction decreases the enantioselectivity of the reaction increases.

1.5.3.5.6 Binaphthalene azepinium salts
Aggarwal has produced a binaphthalene–fused azepinium salt catalyst (68) that is achiral at the nitrogen substituent; this iminium salt catalyst affords 71% ee for 1–phenylcyclohexene and 45% ee for α–methylstilbene.\textsuperscript{128} The Page group postulated they could create a range of N–chiral catalysts that would induce higher levels of enantiocontrol by simply exchanging the biphenyl group for a binaphthalene unit, as in 69.

\begin{center}
\begin{tikzpicture}
% Drawing code here
\end{tikzpicture}
\end{center}

\textit{69, binaphthalene azepinium salt}

The bromomethyl carbaldehyde was prepared from commercial (R) or (S) BINOL. To this, the aminodioxane was added, cyclo-condensing to generate the iminium salt (69).\textsuperscript{142}

Catalyst 69 generated 91% ee for 1–phenylcyclohexene oxide, 95% ee for 1–phenyldihydronaphthylene oxide, and 29% ee for 4-vinylbiphenyl oxide, which is the highest reported ee for the epoxidation of a terminal alkene using an iminium salt catalyst.

The Page group have recently reported a novel sulphone functionalised isoquinolinium derived catalyst (70) that has given high enantiocontrol in the epoxidation of cyclic cis–alkenes under non–aqueous conditions using chloroform as a solvent.\textsuperscript{143}
High yields of up to 86% and up to 97% ee were obtained. Catalyst 70 has been used to obtain excellent enantiocontrol in the epoxidation of 6–cyano–2,2-dimethylbenzopyran. The resulting epoxide is a useful intermediate, which when subjected to ring opening gives access to levcromakalim, a biologically active antihypertensive agent (Scheme 37).\textsuperscript{143}

\textit{Scheme 37}

Azepinium binaphthalene iminium salt catalysts have generated some of the highest enantioselectivities for iminium salt catalysed epoxidation. Even with decreased catalyst loading; a 0.1 mol\% loading of catalyst 67 gives 88% ee for 1–phenylcyclohexene.
1.5.3.6 Lacour’s trisphat counterion chiral iminium salt catalysts

Lacour’s research utilised the same iminium ion developed by Page; his derivation was to use a TRISPHAT [tris(tetrachlorobenzenediolato)phosphate(v)] counter-ion to pair with the active iminium species. The TRISPHAT anion and subsequent catalyst pairings are lipophilic and have preference for the less polar organic layer. The pairing of the enantiomerically pure TRISPHAT anion with a biphenyl catalyst leads to the formation of diastereoisomeric intramolecular and/or intermolecular interactions, which shifts the conformational equilibrium towards one preferred, (Ra) or (Sa), diastereoisomer of the active catalyst’s biaryl backbone. With one diastereoisomer preferred the observed enantiocontrol might increase. The binaphthyl based catalysts, with their fixed axial chirality, would not benefit from such pairing.

The TRISPHAT anion was paired with biphenyl catalyst, matched (Sa,S) binaphthyl catalyst, mis-matched (Ra,S) binaphthyl catalyst and mis-matched (Sa,R) catalyst. Catalyst induced up to 54% and 68% ee when using 1-phenylcyclohexane and 1,2-dihydronaphthylene respectively as the alkene substrates. Matched catalyst induced 81% and 83% ee, whilst its atropisomer, mis-matched,
induced 79% and 78% ee over the same alkene substrates. Catalyst 75 offers the highest enantiocontrol for a TRISPHAT counter ion iminium salt catalyst giving 86% and 87% ee.\textsuperscript{146} It was observed that the TRISPHAT counter-ion decreases the enantiocontrol induced by the selected iminium salt catalysts.\textsuperscript{147}

\begin{center}
\includegraphics[width=0.5\textwidth]{image}
\end{center}

76

In a small number of cases, amine 76 displayed similar enantioselectivity to its iminium salt catalyst derivative 73. Amine 76 imparted 80% ee for 1,2-dihydronaphthylene oxide and 49% ee for methyl trans stilbene oxide.

1.5.4 Amine catalysed Epoxidation

1.5.4.1 Initial observations by Aggarwal

Aggarwal has also examined amine–catalysed epoxidation; his initial observations, based on control epoxidations, showed that a chosen secondary amine hydrogen chloride salt, with added bicarbonate salt and Oxone®, could mediate the alkene epoxidation alone. Condensation with a selected ketone, as previously shown, to produce the iminium salt catalyst was not required. This observation resulted in the trial of a multitude of secondary amines for activity.\textsuperscript{148}

\begin{center}
\includegraphics[width=0.3\textwidth]{image}
\end{center}

77, dinaphthyl–methyl pyrrolidine
Aggarwal produced an amine hydrogen chloride salt catalyst based on the most reactive and enantioselective secondary amine; this was a chiral dinaphthyl–methyl pyrrolidinium salt (77). Using their optimised conditions, 77 mediated epoxidation, inducing up to 66% ee.

Mechanistic studies of the oxidation process were completed. It was observed that on the addition of Oxone® to the chiral amine, the active oxidant, persulphonic acid, becomes hydrogen bonded to the amine salt, this may occur in three differing orientations (Figure 78). A reduction in enantioselectivity may be envisaged due to the presence of these three competing transition states. The alkene then approaches the amine–peracid complex, and oxygen transfer occurs (Scheme 38).
1.5.4.2 Developments by Yang

Whilst developing the *in situ* generation of iminium salt catalysts for asymmetric epoxidation, Yang also observed that control experiments involving just an amine facilitated the production of an epoxide from the alkene substrate. Following these observations Yang examined a variety of amines to determine their activity in asymmetric epoxidation. Yang found that cyclic secondary amines gave the highest levels of enantiocontrol, especially cyclic secondary amines containing a $\beta$–hydroxyl group. Yang optimised the process further by screening a range of pyrrolidine analogues for increased levels of enantiocontrol in the epoxidation of *trans*–stilbene. It was observed that amine 79 induced a fair level of enantiocontrol, giving up to 33% $ee$ and 58% conversion.
Further work showed that conversion of the hydroxyl group into the corresponding fluoro group gave catalyst (80) with increased reactivity, which was observed to give enantiocontrol of up to 50% with 100% conversion with 1-phenylcyclohexene (Scheme 39). The enantiocontrol was increased further with the reduction of the temperature to –20 °C, giving up to 60% ee. Yang also completed mechanistic studies similar to those of Aggarwal and agreed that the mechanism does progress through a pyrrolidinium complex.151

1.5.4.3 Jørgensen’s oxidation of α,β-unsaturated ketones.

Jørgensen produced his first organo-catalytic asymmetric epoxidation of α,β-unsaturated ketones using various peroxides as the stoichiometric oxidant.152 A number of chiral amines were examined as facilitators for the asymmetric epoxidation of cinnamic aldehyde. It was once more observed that a chiral pyrrolidine derivative, amine 80, in conjunction with hydrogen peroxide afforded good ee, up to 96% ee in the product epoxide (Scheme 39).
Further investigations utilising amine 80 and hydrogen peroxide gave epoxides with high enantiomeric control (96 – 98%) and yield (60 – 90%). Jørgensen also published their mechanistic rationale for this procedure.

The mechanism is postulated as involving initial nucleophilic attack by the amine on the aldehyde to generate the iminium intermediate. Nucleophilic attack of the peroxide on the β–carbon generates the chiral enamine intermediate. Nucleophile attack by the enamine at the most electrophilic per–oxygen then gives the epoxy–iminium adduct. Hydrolysis of the iminium functionality generates the desired epoxy–aldehyde and the amine catalyst (Scheme 41).

The solvent of choice is usually dichloromethane, but recently Jørgensen has published a modification in which the reaction can be completed in an aqueous medium (ethanol/water) using amine 80 and hydrogen peroxide as a stoichiometric oxidant, generating up to 96% ee.\textsuperscript{153}
Cordova has also investigated related catalytic systems using catalysts 82 and 83 similar result have been published using sodium percarbonate and hydrogen peroxide as stoichiometric oxidants, generating up to 98% ee.¹⁵⁴

2 Results and discussion.

The Page group’s epoxidation research has centred on the development of two core ideas. Firstly the development of highly enantioselective iminium salt organocatalysts for use in the asymmetric epoxidation of alkenes. To date several catalysts have given greater than 90% enantiocontrol, the most enantioselective catalyst, 1, has given up to 97% ee in the epoxidation of 6-cyano-2,2-dimethylbenzopyran (Scheme 1).

\[

\text{O}
\end{array} \\
\text{Catalyst 1, 97% ee}
\]

Scheme 1

The second field of study is in the development of novel oxidative systems for use with our enantioselective catalysts. To date the TPPP oxidative system has given the highest enantioselectivity of all oxidants screened, up to 97% ee (Scheme 1).

The work described in this thesis is an extension of the work previously completed and is novel within the Page group. The first two sections of this chapter describe the efforts made by the author to develop new aqueous oxidative systems using hydrogen peroxide and sodium hypochlorite as stoichiometric oxidants. This would enable the constraints of other universal oxidants such as Oxone® to be lifted and potentially increased enantiocontrol to be achieved. It also would give us insight into the factors which organocatalysed oxidative systems facilitate oxygen transfer (Scheme 2).
The third and fourth sections of this chapter describe the efforts made towards the synthesis of catalyst 2, a sub-structure of catalyst 3, inducing up to 95% ee on our test substrate 1-phenylcyclohexene, and catalyst 4, a novel catalyst based on the biphenyl backbone seen in catalyst 5, the most effective biphenyl iminium salt, which induces up to 60% ee with our test substrate. We anticipated that further research into catalyst design would enable us to determine how steric and electronic factors influence enantiocontrol, both intra- and inter-molecularly, with respect to the organocatalyst and in achieving high enantioselectivity.

The standard iminium salt epoxidation conditions employ the triple salt Oxone® \((2\text{KHSO}_5 \cdot \text{KHSO}_4 \cdot \text{K}_2\text{SO}_4)\) as a stoichiometric oxidant, sodium carbonate, and acetonitrile:water as the solvent mixture (Scheme 3). The presence of water was essential for Oxone® solubility, and the base was essential for the epoxidation reaction to proceed. The major limitation to this system was the restricted range of temperatures at which the epoxidation can be performed (0 °C to room temperature). The upper limit was determined by the stability of Oxone®, which decomposes relatively quickly in the basic medium at room temperature. The lower limit was determined by the use of the aqueous medium: the
typical ratios of acetonitrile to water solvent used as solvent lie between 1:1 and 10:1, and the medium, at a ratio of 1:1, freezes at around – 8 °C. A large quantity of inorganic by-product was also generated from the decomposition of the oxidant.\(^1\)

![Scheme 3](image)

**Scheme 3**

Iminium salt catalysts 6 and 7 mediate the epoxidation of 1-phenylcyclohexene in 41% and 59% ee when using Oxone\(^\text{®}\) as the oxidant. We have recently prepared and utilised the tetraphenylphosphonium salt (TPPP) of monoperoxy sulphate as a stoichiometric oxidant that was soluble in organic solvents. Enantiocontrol increases in these cases when using TPPP, in a solution of dichloromethane below 0 °C, to 43% and 67% ee respectively.
2.1 Optimisation of new systems for catalytic asymmetric epoxidation.

2.1.1 Formulation of the iminium salt catalysts

The synthesis of iminium salt catalysts 6 and 7 is shown below (Schemes 4, 5 and 6). The first step was the construction of aminodioxane unit. Commercially available (S)-(–)-2-Amino-3-phenyl-1-propandiol 8 was N-protected with methyl formate to give 9 which was not isolated, subsequent diol protection with dimethoxypropane gave the 6-membered acetal unit 10. Finally, N-deprotection using hydrazine hydrate gave the aminodioxane unit 11 in 87% yield over three steps.

Reagents and conditions; (a) MeOH, NaOMe, MeOCHO, rt, 2 hrs. (b) Acetone, 2,2-dimethoxypropane, HBr, rt, 4 hrs. (c) hydrazine hydrate, Δ, 4 hrs.

Scheme 4

The synthesis of catalyst 6 was initiated by the ring cleavage of isochroman 12 with bromine to generate the bromoaldehyde 13. On cyclo-condensation with the aminodioxane 11 and anion exchange with sodium tetraphenylborate, the desired iminium salt catalyst was generated in 54% yield over two steps.
Catalyst 7 was produced using bis(hydroxymethyl)biphenyl 14 as the starting material. Exposure to aqueous hydrogen bromide generated the dibrominated intermediate 15. The condensation of the aminodioxane 11 gave the tertiary amine 16, which was oxidised to the iminium salt with N-bromosuccinimide. Subsequent anion exchange gave iminium salt catalyst 7 in 82% yield over three steps.
2.1.2 The utilisation of hydrogen peroxide as a stoichiometric oxidant.

We were keen to investigate other potential oxidants in order to widen the range of usable reaction conditions, but most oxidants either do not drive the catalysed reaction or generate considerable achiral product through background oxidation of the alkene substrates. Hydrogen peroxide is perhaps the second most environmentally friendly oxidant available after oxygen, in terms of by-products, and its use as a stoichiometric oxidant would allow an inexpensive and ‘green’ process to be developed. Hydrogen peroxide is a standard reagent used to oxidise electron-deficient alkenes, such as enones and conjugated esters, to their corresponding epoxides in the presence of base and polyleucine catalyst (known as the Julia olefination).
In order to develop a hydrogen peroxide-driven system using oxaziridinium salts as catalyst, several problems had to be addressed. Unlike Oxone®, hydrogen peroxide does not induce epoxidation in the absence of base. A co–catalyst that could be oxidised to a species that is capable of oxygen transfer to an iminium salt was therefore required. In the solid state, sodium percarbonate has been shown by X-ray crystallographic analysis to consist of a layered solid corresponding to \( \text{Na}_2\text{CO}_4\cdot1.5\ \text{H}_2\text{O} \).\(^4\) Richardson and Yao have since reported that, upon addition of hydrogen peroxide to sodium hydrogen carbonate, an equilibrium between sodium hydrogen carbonate and the corresponding percarbonate was established (Equation 1).\(^5\)

\[
\text{H}_2\text{O}_2 \ + \ \text{HCO}_3^- \ \rightleftharpoons \ \text{HCO}_4^- \ + \ \text{H}_2\text{O}
\]

*Equation 1*

We reasoned that the percarbonate could, in principle, oxidise an iminium salt to the corresponding oxaziridinium salt,\(^6\) expelling carbonate as the leaving group. Upon trialling this we were pleased to find that commercial sodium percarbonate does indeed drive the reaction when present in large excess. The oxaziridinium salt could then directly oxidise the alkene substrate to the corresponding epoxide. The essential features of this proposed double catalytic cycle are illustrated in Scheme 7.

*Scheme 7, Pathway A*
We were pleased to find that initial experiments utilising hydrogen peroxide (50%, 6 equiv.) and sodium hydrogen carbonate (0.2 equiv.) in an acetonitrile:water (9:1) solvent system using catalyst 6 (10 mol%) induced asymmetric epoxidation of 1-phenylcyclohexene with up to 22% ee at 20 °C.

2.1.2.1 Effects of the base on the reaction

Previous work in investigating the ability of hydrogen peroxide to oxidise an iminium salt to the oxaziridinium salt in the presence of an alkene showed no evidence of epoxidation in the absence of base. In this context, we have tested several bases as possible promoters (Table 1). Our initial reactions were completed at both 0 °C and 20 °C, using 0.2 equivalents of a range of mediators, including potassium hydrogen phosphate, potassium hydrogen sulphate, and sodium and potassium sulphates, in addition to those indicated in the table. From our previous work using Oxone® as the stoichiometric oxidant, we found that a 9:1 ratio in the acetonitrile:water solvent system gave optimum conversion and ee, and that catalyst 7 provided superior enantioselectivities to catalyst 6. We therefore used this solvent ratio and catalyst 7 in our investigation.

* * epoxidation conditions: Iminium salt catalyst 7 (10 mol%), hydrogen peroxide (50%, 6 equiv.). Base, Acetonitrile:H$_2$O (9:1), 24 hours. * Conversions and enantiomeric excesses were determined from the chiral GC–FID spectra by comparison of the alkene/epoxide and epoxide/epoxide peak areas respectively; the major enantiomer generated was the (1S,2S) epoxide.
Background epoxidation utilising 0.2 equivalents of base, at 0 °C over 24 hours, in the absence of any catalyst, was not observed for sodium, potassium, or lithium carbonates, but was observed at a low level when using caesium or rubidium carbonates (<5%), and ammonium bicarbonate (approx 2%). At room temperature, over 24 hours, the extent of the background epoxidation varied with the cation used: sodium (<5%), potassium (11%), rubidium (15%), caesium (15%) carbonates, and ammonium bicarbonate (20%). These results suggest that decreasing ion association increases background reaction; large organic cations, and the iminium salt when present, could enhance background epoxidation by this purely physical means, because their size makes interionic distance too large for electrostatic association.

Table 1 shows that the potassium salts at 0 °C provide the highest enantioselectivity for reasonable conversions, giving 34% ee (KOH), 35% ee (KHCO3), and 39% ee (K2CO3). Rubidium and caesium carbonate also gave good enantiocontrol, but show the highest level of background epoxidation at 0 °C, although this was still low at <5%. The sodium salts show decreased enantiocontrol compared with their analogous potassium salts.

It appears that the enantioselectivity achieved was largely independent of the type of mediator (HCO3−, CO32− or OH−) used to promote the reaction. As we have previously established, in the absence of base no epoxidation occurs, and indeed even experiments containing very small amounts of base (0.01 equiv.) showed no epoxidation (entry 3). When the amount of base was increased to 0.1 equivalents, the desired epoxidation reaction furnished 1-phenylcyclohexene oxide with enantioselectivities of 35% ee for NaHCO3, 33% ee for Na2CO3 and 28% ee for NaOH. We also observed that for any base added at a level greater than 0.1 equivalents (up to 2 equivalents), the ee remained approximately constant.

For the carbonate bases we next tested the effect of the accompanying counter-ion, but little variation in the product ee was observed (36% ee for Cs2CO3, 35% ee for Ru2CO3, 39% ee for K2CO3, 31% ee for Na2CO3). Interestingly, similar levels of enantioselectivity were observed with rubidium and caesium carbonates despite increased background epoxidation in the absence of catalyst. Presumably the presence of an iminium salt catalyst offers a lower energy pathway, leading to asymmetric epoxidation.
In interpreting the observations it must be borne in mind that several equilibria determine the availability of the key species responsible for generating the oxaziridinium cations. The interrelation of these is shown in Scheme 9, in which are indicated pK-values for some of the individual processes in water that can be deduced from literature values for the pKₐ-values of water, hydrogen peroxide and carbonic acid, together with that for the equilibrium in Equation 1.

For a solution of bicarbonate and hydrogen peroxide, formally 1 M in each at a pH such that we do not need to consider the presence of carbonate or percarbonate dianions (a fixed pH in the range 10-11), the ratio of \([\text{HCO}_3^-]\) to \([\text{HCO}_4^-]\) is ca. 3:1, i.e. approx. 0.75M H-carbonate to 0.25M H-percarbonate. Each of these species is in equilibrium with \([\text{CO}_2^-]\) ions and, \([\text{OH}^-]\) ions or \([\text{HOO}^-]\) ions to a small degree, the effective equilibrium constant in the case of \([\text{HCO}_3^-]\) being \(2.3 \times 10^{-8}\), and that in the case of \([\text{HCO}_4^-]\) \(7.2 \times 10^{-4}\). The \([\text{HO}^-]+[\text{HOO}^-]\) concentrations will therefore be given by the square root of \(K_c = 1.3 \times 10^{-4}\) for \([\text{HO}^-]\) and \(1.35 \times 10^{-2}\) for \([\text{HOO}^-]\). At the autogenerated pH of the solution (ca. 10) any surplus H₂O₂ will contribute to the concentration of \([\text{HOO}^-]\) and this could be as much as the concentration generated by dissociation of \([\text{HCO}_4^-]\). Hence the ratio of \([\text{HCO}_4^-]/[\text{HOO}^-]\) is of the order of 10 – 20. The ratio may perhaps be manipulated by buffering the pH.

Under the reaction conditions the situation will be substantially different because in 90% aqueous MeCN the water activity is much lower than in pure water and this will increase the ratio \([\text{HCO}_4^-]/[\text{HOO}^-]\). Also remember that only the proton transfer processes are effectively instantaneous; additions to and dissociations from CO₂ are relatively slow (half-lives of the order of minutes to hours, depending on solvent) compared with the proton transfers.

Bearing in mind that the hydrogen percarbonate anion can exist in two prototropic forms, \(\text{HO}^-\text{CO}-\text{O}^-\) and \(\text{HO}-\text{CO}-\text{OO}^-\) only the less stable of which (the latter) is expected to be an effective oxidising agent for the iminium cation, and that hydroperoxide anion may be intrinsically more reactive, the balance of reaction between pathways A and B in Scheme 9 may be substantially less than 20. Percarbonate and hydroperoxide anions can be expected to convert chiral iminium salts to the oxaziridinium species with different facial
selectivities, giving different diastereoisomeric excesses. Since each diastereoisomeric oxaziridinium cation will have its own overall reactivity and enantioselectivity in transferring an oxygen atom to the alkene, the enantioselection observed in the epoxide produced in iminium ion-catalysed oxidation was expected to be dependent on the choice of oxidant. Different enantioselectivities are thus to be anticipated from iminium ion mediated oxygen transfer using as oxidant Oxone®, hydrogen peroxide in the presence of a carbonate base, and hydrogen peroxide using a strong base capable only of deprotonating it.

Scheme 9

The active oxidant in Oxone® is KHSO₅, and so KHSO₄ was tested to determine if the hydrogen peroxide oxidant could oxidise the potassium salt to the active persulfate in situ, in the hope that this system might give similar enantioselectivity to the Oxone® epoxidation system. When Na₂SO₄, K₂SO₄ and KHSO₄ were used in test reactions poor levels of conversion to the respective epoxides (<15%) were observed.
2.1.2.2 Effect of temperature on the reaction

We next investigated the effect of temperature on the enantioselectivity in epoxidation reactions carried out between –10 and 30 °C (Table 2). A small increase in enantioselectivity was observed as the temperature was reduced. As the temperature decreased the rate also decreased, requiring one week for the reaction to reach completion at 0 °C, whereas full conversion to the epoxide at 20 °C was observed in less than 24 hours. At 30 °C, the reaction was complete after 2.5 hours. Catalyst 7 showed increased levels of enantioselectivity over catalyst 6, but 6 generally gave better conversion to the epoxide at lower temperatures.

2.1.2.3  Effects of solvents on the reaction

2.1.2.3.1  Effects of the ratio of co-solvents used

Our first reactions were carried out using an acetonitrile:water (9:1) solvent system. We have investigated the effect of the proportion of water on the enantioselectivity of the epoxidation process (Scheme 10).

![Scheme 10](image)

Reactions were carried out using six molar equivalents of hydrogen peroxide from a 50% aqueous solution; the results are shown in Table 3. In each case the volumes of water and hydrogen peroxide in the reagent were taken into account when determining the proportion of water present in the total solvent volume. A 0% water solvent system was achieved by the use of ethereal hydrogen peroxide.

*a Epoxidation conditions: Iminium salt catalyst 7 (10 mol%), hydrogen peroxide (50%, 6 equiv.). NaHCO₃ (0.2 equiv.), Acetonitrile:H₂O, 0 °C, 24 hours.  b Conversions and enantiomeric excesses were determined from the chiral GC–FID spectra by comparison of the alkene/epoxide and epoxide/epoxide peak areas respectively. The major enantiomer generated was the (1S,2S) epoxide as deduced by both GC-FID and optical rotation against enantiopure standards. c Ethereal hydrogen peroxide used; reaction volume contained 13% Et₂O. d K₂CO₃ used as base.

The table clearly shows that increasing the proportion of water present decreases the observed ee under these conditions. This was in sharp contrast to our aqueous Oxone® system, in which ee was unaffected by the proportion of water, but in which the rate of reaction increases sharply as the proportion of water was increased. 7b Although many hours or even days may be required for these reactions to reach completion, the enantioselectivity of the epoxide product remained constant throughout this time. Maximum enantioselectivity was obtained under the anhydrous reaction conditions (56% ee); this was comparable to the Oxone®-mediated system (60% ee), when using 1-
phenylcyclohexene as the substrate and iminium salt 7 as catalyst. This effect of water content with respect to enantioselectivity may perhaps be interpreted in terms of water influencing the stereochemical course of the reaction by affecting the diastereofacial selectivity of addition of the peroxy anion to the iminium carbon atom (Scheme 8, Pathway B), for example by diastereofacially selective co-ordination of water molecules to the electron-deficient iminium units. Changing the solvent will, of course alter the equilibria shown in Scheme 9, perhaps slowing down the percarbonate generation relative to the fast proton transfers; thus hydroperoxide may become relatively more important than percarbonate, and this also might reduce enantioselectivity. Further, anions generally are less active in aqueous solvents than in dipolar aprotic ones, and this might slow down the addition of percarbonate or hydroperoxide to the iminium ion.
2.1.2.3.2 Effects of change of organic co-solvent

A range of reactions with different co-solvents was carried out using catalyst 7, hydrogen peroxide, and potassium carbonate, at –5 °C to prevent background epoxidation (Table 4)

a Epoxidation conditions: Iminium salt catalyst 7 (10 mol%), hydrogen peroxide (50%, 6 equiv., K₂CO₃ (0.2 equiv.), solvent (1 ml), –5 °C, 24 hours. b Conversions were evaluated from the chiral GC–FID spectra by comparison of the alkene and epoxide peak areas. c Enantiomeric excesses were determined by chiral GC–FID spectra by comparison of the two epoxide peak areas. The major enantiomer generated was the (1S,2S) epoxide as deduced by both GC-FID and optical rotation against enantiopure standards.

It appears that solvents that provide good base solubility and also provide a homogenous reaction mixture increase the enantioselectivity of the epoxidation, for example acetone (53% ee), methanol (44% ee), and acetonitrile (37% ee).
2.1.2.4 Conclusion

We have successfully demonstrated the use of hydrogen peroxide as the stoichiometric oxidant in iminium salt-catalysed asymmetric epoxidation, providing a cheaper and greener alternative to Oxone®. The reaction was promoted by a catalytic amount of inorganic mediators such as carbonate, hydrogen carbonate and hydroxide. The enantioselectivity of the reaction was largely independent of the amount of base and catalyst, and the nature of cation associated with the base. In contrast, water content and temperature appear to have the greatest impact on the enantioselectivity and rate. We believe that this process operates through a double catalytic cycle (Scheme 2).

Optimisation of the oxidative system enabled asymmetric epoxidation of 1-phenylcyclohexene with 56% ee utilising catalyst 7 and ethereal hydrogen peroxide in the absence of water at –5 °C (Scheme 11). Further work on alternative oxidants and catalysts towards more enantioselective systems is in progress.
2.1.3 The utilisation of sodium hypochlorite as an organic oxidant.

During our work with hydrogen peroxide, we observed that carbonate salts co-catalysed the epoxidation effectively, with no background epoxidation being observed when reactions were carried out at temperatures of up to 5 °C. We suggested that a double catalytic cycle may operate in these processes, with percarbonate providing an intermediate oxidising stage. We conjectured that sodium hypochlorite might provide an alternative stoichiometric oxidant for our iminium salt-catalysed systems by generating a percarbonate oxidant in-situ in the presence of a carbonate salt.

Sodium hypochlorite is inexpensive, relatively safe, and has high oxygen content. In the form of commercial bleach it can oxidize electron-deficient alkenes, such as enones and conjugated esters, to their corresponding epoxides with the addition of catalytic base, but does not generally directly oxidize electron-rich alkenes to their corresponding epoxides. Bleach has been used as an oxidant in asymmetric epoxidation using a range of catalysts including chiral salen complexes, manganese porphyrin complexes, and quaternary ammonium salts. There is also precedent for the use of other hypochlorite oxidants such as potassium hypochlorite for oxygen transfer, for example oxidations of alcohols to ketones, aldehydes to acid chlorides, ketones to carboxylic acids, sulfides to sulfoxides, phosphines and phosphites to phosphine oxides and phosphates. Donohoe has reported the use of potassium hypochlorite as an oxidant for catalytic asymmetric aminohydroxylation, and Corey has reported asymmetric epoxidation catalysed by dihydrocinchonidinium salts using potassium hypochlorite as oxidant.

Sodium hypochlorite itself does not directly oxidise simple alkenes under our reaction conditions: blank reactions in the presence of potassium carbonate, but in the absence of an iminium salt catalyst, show no conversion to the epoxide over 24 hours. Under the same conditions and in the presence of the iminium salt, epoxidation was observed.

It was therefore postulated that sodium hypochlorite could generate the percarbonate in-situ (Equation 2), which in turn could oxidise the iminium salt to the oxaziridinium salt thus generating a species capable of oxygen transfer to the alkene substrate.
NaOCl + HCO₃⁻ ⇌ NaCl + HCO₄⁻  

*Equation 2*

Two possible catalytic cycles are illustrated in Scheme 12, Pathway A and Scheme 13, Pathway B for the proposed process. Hypochlorite may generate percarbonate, which then acts as the oxygen transfer agent, followed by oxaziridinium ion formation (Scheme 12, Pathway A); such a double catalytic cycle involving a second mediator does not appear to have been previously proposed for other processes involving hypochlorite. Alternatively, hypochlorite may add directly to the iminium unit (Scheme 13, Pathway B). Both pathways involve expulsion of a leaving group to generate the oxaziridinium intermediates, potentially as a pair of diastereoisomers, each of which may induce asymmetric oxygen transfer to a substrate. These diastereoisomers would be expected to display different enantioselectivities in any such reaction; the observed ee in each case may therefore be an aggregate of the two.

*Scheme 12, Pathway A*
Initial experiments carried out at room temperature using sodium hypochlorite solution (13%, 3 equiv.) as stoichiometric oxidant, potassium carbonate (0.25 equiv.) as mediator, and iminium salt catalyst 7 (10 mol%) in an acetonitrile medium induced asymmetric epoxidation of 1-phenylcyclohexene with up to 50% ee (Scheme 14). We were encouraged by this observation to investigate the parameters affecting this potentially attractive reaction system.

**Scheme 14**

**The effect of inorganic mediator on asymmetric epoxidation**

Mixtures containing iminium salt 7 and sodium hypochlorite in the presence of an alkene substrate but in the absence of an inorganic mediator showed no conversion to the corresponding epoxides. Therefore sodium hypochlorite, like hydrogen peroxide under similar conditions, is unable to drive the epoxidation process, and thus presumably does not oxidize iminium salts to oxaziridinium salts, in the absence of inorganic mediator. We
therefore investigated the effects on the reactions of several added mediators in reactions carried out over 24 hours (Table 5).

Epoxidation conditions: iminium salt (10 mol%), sodium hypochlorite (13%, 6 equiv.), mediator (0.25 equiv.), dichloromethane (1 ml) 0 °C, 24 h. Conversions were evaluated by GC analysis based upon alkene and epoxide content. Enantiomeric excesses were determined by chiral GC analysis; the major enantiomer was the (1S,2S)-epoxide.

Rewardingly, the reactions proceeded smoothly when a mediator was included, and the enantioselectivity observed was largely independent of the type of mediator (hydrogen carbonate, carbonate or hydroxide) used to promote the reaction. Experiments containing a very low proportion of mediator (0.01 equiv.) showed minimal conversion to the epoxide. When the proportion of mediator was increased to 0.25 equivalents, the reaction furnished 1-phenylcyclohexene oxide with 68% ee with K₂CO₃, 60% ee with NaHCO₃, and 67% ee with KOH. For any mediator, the ee remained constant when the mediator was added in greater proportion than 0.1 equivalents. We concluded that, in those cases using carbonates as bases, percarbonate may be generated, and this may mediate the generation of an oxaziridinium ion. The large variation in conversions and to a lesser extent on the
enantioselectivity, due to the change of mediator may reflect that the conversion mirrors rate of reaction. The rate of reaction is dependent on the ease of generation of the oxaziridinium species, and this would be affected by factors such as the multiphase structure, ion association, identity of the peroxo nucleophile generated; while by contrast the ee should be less variable, unless there is a large variation in the direction of attack on the iminium salt using different inorganic mediators.

The effects of solvent and temperature

As potassium carbonate appeared to offer the best ees, together with margins for improvement in both conversions and ees, we chose this mediator for further studies. Several solvents were investigated, with reactions carried out at room temperature and 0 °C using catalyst 7 (Table 6).

Iminium salt Catalyst 7 (10 mol%), sodium hypochlorite (13%, 3 equiv.), K₂CO₃ (0.25 equiv.), solvent (1ml), alkene substrate (1 equiv.). * Conversions and enantiomeric excesses were determined by chiral GC analysis; the major enantiomer was the (1S,2S)-epoxide.
The results presented in table 2 show that acetonitrile facilitates complete conversion to the epoxide in less than 24 hours in the absence of the iminium salt catalyst, perhaps as a result of peroxyimidic acid formation. No such background epoxidation was seen over the same period when using dichloromethane or chloroform as the reaction solvent. Interestingly, in the presence of catalyst 7, the epoxide was obtained in 50% ee at rt and 56% ee at 0 °C in acetonitrile solvent, despite the ready background pathway, the presence of the iminium salt catalyst presumably offering a lower energy pathway for reaction, leading to asymmetric epoxidation. When using dichloromethane as the reaction solvent, iminium salt catalyst 7 induces epoxidation with 60% ee at rt and 68% ee at 0 °C. Oxygen transfer, for example from percarbonate, to the iminium ion may take place at the solvent-solvent interface (Scheme 15). Alternatively, the iminium salts may act as phase transfer agents, the oxidation to oxaziridinium species then taking place in the aqueous phase before return of the oxaziridinium ion to the organic phase. Assuming that hypochlorite will be largely contained in the aqueous phase, the oxaziridinium species would then become the dominant oxidant in the organic phase.

It seems likely that the decreased enantiocontrol in the acetonitrile reaction was due to background epoxidation, rather than a genuine solvent effect. Use of chloroform, however, clearly results in poorer induced enantioselectivity, although chloroform does not promote background epoxidation. We have previously observed excellent enantiocontrol when using chloroform as the solvent under non-aqueous conditions, with TPPP as stoichiometric oxidant.8,9
Stronger hypochlorite oxidants such as potassium hypochlorite and t-butyl hypochlorite have also shown precedent for oxygen transfer.\(^{14,22}\) Therefore both oxidants were tested for their capacity as an oxidant within our current conditions (Scheme 16). Unfortunately t-butyl hypochlorite proved too strong an oxidant as full conversion to the epoxide was observed without inducing enantioselectivity.

In previous work it was observed that when attempting to oxidise cis-substituted alkenes, the utilisation of iminium salt catalyst 1, a sulphone derivative of catalyst 6, gave high levels of enantiocontrol. More interestingly, when using chloroform as a solvent, catalyst 1 generated the opposite enantiomer of the desired epoxide. When epoxidation was attempted in any other solvent the enantiocontrol decreased and the stereochemistry of the epoxide product reverted back to that of which the parent catalyst 6 yielded.
With the new sodium hypochlorite system giving good enantiocontrol when used in conjunction with chloroform and iminium salt catalyst 7 (up to 47%), it was proposed that the use of iminium salt 1 when used under these same sodium hypochlorite conditions would give encouraging results.

Thiomicamine, 17 was formate protected at the nitrogen (18, Scheme 17), allowing subsequent $p$-TSA catalysed diol protection, 19 with 2,2-dimethoxypropane. The thiol was oxidised to the sulphone, 20 with $m$-CPBA. The formate protecting group was removed using hydrazine hydrate generating sulphone aminodioxane 21 in 26% over four steps.
Reagents and conditions; (a) MeOH, NaOMe, Methyl formate, rt, 2 hrs. (b) Acetone, 2,2-DMP, p-TSA, rt, 4 hrs. (c) m-CPBA, DCM, rt, 16 hrs. (d) N₂H₄, Δ, 4hrs.

Scheme 17

Isochroman was ring opened with bromine to generate the phenyl bromo aldehyde 23 (Scheme 18). The sulphone aminodioxane 21 was then condensed with bromoaldehyde 23 to yield iminium salt 1 in 34%.
Catalyst 1, 6 and 7 were then tested with in the new oxidative system to observe their effectiveness on a range of test substrates (Table 7).

It was observed that using iminium salt catalyst 7 in dichloromethane gave the best reaction profile when using sodium hypochlorite as the oxidant giving up to 68 % conversion, and up to 71 % ee for 2,3-dihyдонaphthylene. Decreased enantioselectivities were observed when using either acetonitrile or chloroform as the solvent. Reversal of enantiocontrol was not observed for any substrate used when employing salt catalyst 1 and chloroform as the solvent.

**a** epoxidation conditions: Iminium salt catalyst (10 mol%), Sodium hypochlorite (13%, 6 equiv.), K₂CO₃ (0.25 equiv.), Solvent (1 ml) 0°C, 24 hours. **b** Enantiomeric excesses were determined by chiral GC–FID spectra by comparison of the two epoxide peak areas. **c** Conversions were evaluated from the chiral GC–FID spectra by comparison of the alkene and epoxide peak areas. **d** Absolute configurations of the major enantiomers were determined by comparison of both optical rotation and GC-FID with those reported in the literature.
With the new sodium hypochlorite oxidative system inducing up to 71% ee, the next step was to assess catalyst 3 with in this system (Scheme 2), which induces up to 95% ee under the original Oxone® conditions.

When catalyst 3 was used under the sodium hypochlorite conditions, little conversion to the epoxide was observed. This was due to the decomposition of the binaphthalene based catalyst under the reaction conditions over the prolonged 24 hour reaction time.

**Scheme 19**

2.1.3.1 Conclusion.

The addition of the K$_2$CO$_3$ elevates the pH of the reaction to ≥ 11.0. This rise in pH facilitates the generation of hypochlorite anions in the reaction mixture. The hypochlorite anion then follows one of the two hypothesised pathways (Scheme 12, Pathway A and Scheme 13, Pathway B) via either an aminohypochlorite adduct or an aminopercarbonate adduct. Both pathways collapse to generate the oxaziridinium intermediate as a pair of diastereoisomers with the expulsion of an appropriate leaving group. These diastereoisomers almost certainly operate through different transition states during the oxygen transfer to the substrate and with different kinetics therefore inducing different enantioselectivities. The observed ee in each case was an average of the two processes.
Commercial sodium hypochlorite has shown to be a useful stoichiometric oxidant in iminium salt-catalysed asymmetric epoxidation. Addition of sodium hypochlorite to a carbonate salt forms an extremely reactive species capable of oxidising iminium salts to their corresponding oxaziridinium salt. Optimization of the oxidative system has enabled asymmetric epoxidation with good enantiocontrol of up to 71%, in the epoxidation of 2,3-dihyronaphthylene when using iminium salt 7. The overall process enjoys simplicity and environment friendliness that may be of benefit to both industrial and academic laboratories.
2.2 New novel catalysts for catalytic asymmetric epoxidation.

Over the last ten years Page has developed a range of iminium salt catalysts incorporating a chiral substituent at the iminium nitrogen atom. The presence of chirality \( \alpha \) to the iminium nitrogen has been shown to induce increased enantiocntrol in epoxidation reactions compared to catalysts that contain an \( N \)-achiral substituent.

We hypothesised that more complex chiral groupings \( \alpha \) to the iminium nitrogen and at other strategic locations may further increase the enantioselectivity induced in asymmetric epoxidation.

2.2.1 Dihydroisoquinolinium salt catalysts with \( \alpha \) nitrogen chirality.

Work within the group was aimed towards the generation of dihydroisoquinolinium salt catalysts with chiral functionality incorporated into the dihydroisoquinolinium ring and also \( \alpha \) to the iminium nitrogen atom. Iminium salt 24 is one such target.

![Structure of iminium salt 24](image)

With iminium salt 24 identified, a retro-synthetic outline was postulated (Scheme 20).
The desired iminium salt 24 would be generated by quarternisation of 25 with a suitable alkyl group. Oxidation of amine 26 with NBS would generate imine 25, the former (26) would be generated by the acid deprotection and reduction of 27. Using Seebach methodology, base deprotonation of 28 α to the carbonyl group and trapping with the introduction of ‘RX’ would generate the substituted tricycle 27 maintaining the chirality present in 29. And finally the first hypothesised synthetic step would be the cyclisation of enantiomerically pure tetrahydroisoquinoline 29 with pivaldehyde so generating the t-buty1 acetal 28.

Using 1,2,3,4-tetrahydroisoquinoline-3-carboxylic acid (29) as the starting material, attempts to cyclise the amino and carboxylic acid functionalities with pivaldehyde under Dean and Stark conditions were unsuccessful (Scheme 21). A range of reaction conditions using both the acid and its sodium salt, were attempted in an effort to cyclise the starting material; unfortunately these conditions were all unsuccessful (Table 8). Further attempts to prepare this family of catalysts was therefore abandoned.
Reagents and conditions; (a) Pivaldehyde (for conditions see Table 8).

2.2.2 Iminium salt catalysts based on a biphenyl azepinium backbone

Page has reported that iminium salt catalysts based on a biphenyl skeleton fused with an azepinium salt induce good enantioselectivity and excellent reactivity in terms of conversion of an alkene to the corresponding epoxide (Scheme 22).

\textit{Scheme 22}

It was evident that iminium salt catalysts containing an \(N\)-chiral appendage gave increased enantiocontrol over chiral catalysts containing an achiral \(N\)-substituent. The approach of the oxidant or the alkene substrate to the iminium or the oxaziridinium salt (respectively) is presumably directed electronically or sterically by this \(\alpha\)-chirality, therefore increasing enantiocontrol.

The biphenyl azepinium catalysts contain a methylene group \(\alpha\) to the nitrogen. It was postulated that the biphenyl azepinium iminium bond (5) could undergo Grignard addition to generate the corresponding amine 32, this amine could then be re-oxidised to the iminium salt 31, using NBS (Scheme 23). This would give a second chiral centre \(\alpha\) to the iminium nitrogen, which we hoped would induce increased enantioselectivity by electronic and/or steric interaction with the approaching oxidant or alkene substrate.
Using $N$-isopinocampheyl iminium salt 30 as a model substrate, methyl magnesium bromide was added to the iminium bond. The addition proceeded smoothly generating an inseparable pair of diastereoisomers 33, determined by $^1$H NMR spectroscopy as a 1:1 diastereoisomeric ratio. Reaction of the diastereoisomeric mixture with NBS generated the bromide iminium salt, which underwent ion exchange to generate the tetraphenyl borate iminium salt 34 as a 1:1 mixture of inseparable diastereoisomers. Only oxidation at the methylene carbon atom $\alpha$ to the nitrogen atom was observed, no oxidation is observed at the new chiral carbon centre $\alpha$ to the nitrogen.

**Scheme 23**

This second-generation iminium salt catalyst 34 was tested for its ability to induce enantiocontrol in asymmetric epoxidation of 1-phenylcyclohexene (Scheme 25). Catalyst 34 imparts 61% $ee$ in 1 hour, with 100% conversion to the epoxide. In comparison to the parent catalyst 30, which imparts 29% $ee$ with 100% conversion in less than 30 minutes,
showing that the $\alpha$-substituted iminium salt catalyst 34 induces considerably increased levels of enantioselectivity over 30.

\begin{align*}

\text{35} & \quad 29\% \text{ ee} \\
& \quad 100\% \text{ conv.}
\end{align*}

\begin{align*}
\text{7} & \quad 61\% \text{ ee} \\
& \quad 100\% \text{ conv.}
\end{align*}

Scheme 25

From this encouraging result we focused our attention on the substitution of $N$-dioxane iminium salt catalyst 7, as this has proven to impart higher levels of enantiocontrol than the isopinocampheyl catalyst 30. Several Grignard reagents (MeMgBr, iPrMgBr, PhMgBr & BnMgBr) were added to the iminium bond generating the respective amines 36 – 39 (Scheme 26). NBS oxidation converted the amines into their bromide iminium salts in good yields (40 – 43).
From the V.T. $^{13}$C NMR data, we calculated that the addition of all Grignard reagents to catalyst 7 gave one single diastereoisomer in each case. Epoxidation of our test substrate 1-phenylcyclohexene was completed using these new iminium salt catalysts; the catalysts displaying the highest enantiocontrol were then used to catalyse oxidation of two other representative alkenes (Table 9).

a epoxidation conditions: Iminium salt catalyst (10 mol%), Oxone® (2 equiv.). Na₂CO₃ (4 equiv.), Solvent (1:1 Acetonitrile/H₂O) 0°C. b Enantiomeric excesses were determined by chiral GC–FID spectra by comparison of the two epoxide peak areas. c Conversions were evaluated from the chiral GC–FID spectra by comparison of the alkene and epoxide peak areas. d Absolute configurations of the major enantiomers were determined by comparison of both optical rotation and GC–FID with those reported in the literature. e Enantiomeric excesses were determined by chiral HPLC spectra by comparison of the two epoxide peak areas. f Conversions were evaluated from the 1H NMR spectra by comparison of the alkene and epoxide peak integrations.

The parent catalyst 7 induces up to 61% ee in the epoxidation of 1-phenylcyclohexene. Increased enantiocontrol was observed for all of the second generation catalysts, with catalyst 40, containing an added methyl group, inducing the highest enantiocontrol, giving up to 81% ee and 100% conversion in one hour.

Catalyst 40 shows increased levels of enantiocontrol over its analogues (41 - 43). From the crystal structure (Figure 44), it is evident that there are possibly two factors which contribute to high enantioselectivity. The additional axial methyl substituent C(29) α to the iminium nitrogen N(1) probably impedes the approach of the oxidant from the si face due to the steric hindrance. The methyl group may inhibit approach to the si face of the
iminium bond without hindering the bond rotation of the aminodioxane unit around the, N(1)-C(5). As high enantiocontrol is then directly related to the approach of the alkene towards the ‘free’ re face, any interference with the aminodioxane rotation could directly hinder the re face.

Substitution of larger alkyl and aryl substituents at C(28) may cause higher levels of interference with this aminodioxane rotation, causing enantiocontrol to be reduced as observed in catalysts 41 - 43 presumably by preventing the adoption of the optimal approach control. The introduction of a methyl group appears to be the optimal substitution, balancing si face hindrance with controlled approach of the alkene.

Figure 44, X-ray crystal structure of catalyst 40

The next logical step was to use this methodology to insert a methyl group in to the iminium bond of binaphthyl based iminium salt catalyst 3 (Scheme 27).

R-Binol (45, Scheme 27) was converted to the triflate, 46. This underwent Kumada coupling with methyl magnesium bromide to yield the bismethyl-binaphthyl compound 47. NBS bromination initiated by AIBN generated the dibromobinaphthylene, 48, which was smoothly condensed with aminodioxane 11 to generate the cyclic amine, 49. NBS oxidation of this amine gave the iminium bromide salt 50.
Reagents and conditions; (a) Triflic anhydride, 2,6-lutidine, DMAP, DCM, \(-30^\circ\mathrm{C} \rightarrow \) rt, 4 hrs. (b) MeMgBr, Ni(Cl)\(_2\)(PPh\(_2\))\(_2\), Et\(_2\)O. (c) NBS, CCl\(_4\), AIBN, hv, rt, 5 hrs. (d) 11, THF, TEA, Δ \(\rightarrow\) rt, 5 mins. (e) NBS, DCM, rt, 20 mins.

Scheme 27
The binaphthyl azepinium bromide salt 50 was treated with methyl magnesium bromide, generating the tertiary amine 51 as a pair of diastereoisomers in a 3:2 ratio, determined by $^{13}$C NMR spectroscopy data.

\[ \text{Reagents and conditions; (a) MeMgBr, THF, \,-78 \,^\circ\text{C} \, \text{to rt, 2 hrs.}} \]
\[ (b) \, \text{NBS, DCM, } \Delta, \,15 \, \text{mins.} \]

Scheme 28

Amine 51 was subjected to NBS oxidation generating the desired azepinium bromide salt 52 in good yield as a pair of inseparable diastereoisomers.

Catalyst 52 was then compared to its parent, catalyst 3, as were catalysts 34 and 40 to test for their ability to induce enantioselectivity in the epoxidation of several alkene substrates (Table 10).

</table>
From Table 10 it can be seen that the second generation of iminium salt catalysts induce, in most cases, higher enantiocontrol than the parent catalyst. The addition of a methyl substituent as for catalyst 40, 3, and 34, gives increased enantiocontrol, presumably due to the additional methyl group sterically and/or electronically controlling the approach of either the oxidant and the alkene substrate. This is remarkable in the case of 52 as the catalyst is used as a pair of diastereoisomers. One possible explanation is that one diastereoisomers is far more reactive than the other.

### 2.2.2.1 Conclusion

On reflection, we have observed that the introduction of a chiral carbon atom α to the iminium nitrogen significantly increases the enantiocontrol of azepinium salt catalysts towards epoxidation of unfunctionalised alkenes.

The introduction of an aryl or alkyl substituent may increase the steric hindrance around one of the two prochiral faces available, therefore increasing the preference for formation of one diastereoisomeric oxaziridinium intermediate, and may also help to control the subsequent approach of the alkene substrate.
2.2.3 **Iminium salt catalysts based on a 7,5-fused bicyclic lactam substructure.**

It has been shown that variations to our original biphenyl azepinium salt catalyst substructure have enabled increased levels of enantiocontrol in epoxidation of selected alkenes.

Furthermore, work investigating the impact of a second chiral carbon atom \(\alpha\) to the iminium nitrogen shows increased enantiocontrol over alkene substrates. We therefore postulate that other iminium salt catalyst sub-structures based on the original biphenyl motif but containing multiple chiral carbons \(\alpha\) to the iminium nitrogen could generate high levels of enantioselectivity.

A fundamental problem concerning biphenyl structures is their ability to rotate around the aryl/aryl bond forming two interconverting atropoisomers denoted \(Ra\) and \(Sa\) by Cahn-Ingold-Prelog rules. Recent work has concerned atropo-enantioselective reactions generating a single atropoisomer. Work reported by Lygo on asymmetric phase transfer alkylation\(^{24,25}\) generated catalyst \(53\) by insertion of six bulky substituent’s on the azepinium biphenyl skeleton. This slows the biphenyl aryl/aryl rotation and establishes one thermodynamically favourable atropoisomer. Our group, using catalyst \(53\) as the template, incorporated amino dioxane \(11\) into the biphenyl skeleton, so generating iminium salt catalysts \(54\) and \(55\).\(^{26}\) Under the standard Oxone® conditions 22% and 44% \(ee\) (respectfully) was generated with our test substrate 1-phenylcyclohexene (Scheme 29).
It was observed by V.T. \textsuperscript{1}H NMR spectroscopy that an atropoisomeric mixture of iminium salt catalyst 55 was present, at 20 °C this was 1:10.2 increasing to a ratio of 1:32 at -40 °C, therefore displaying the preference for one atropoisomer, the identity of which is unknown at present.

From this work it was envisaged that if the biphenyl skeleton could be generated atropoenantioselectively without the presence of the bulky substituents, the presence of a single atropoisomer could be sufficiently investigated.
It was reported by Levacher,\textsuperscript{27} that Meyers’ bicyclic lactam methodology was widely used in the stereoselective construction of five- and six-membered ring nitrogen heterocycles.\textsuperscript{28} These lactams provide a number of highly functionalised chiral building blocks that may be used further, in a wide range of stereoselective transformations, resulting in a chiral axis of the biaryl motif in greater than 95% de (Scheme 30). The desired lactam was generated from an amino alcohol condensation with the acetyl bicyclic ester. This acetyl bicyclic ester was further disconnected using Suzuki methodology to give acetyl phenyl boronic acid and 2-iodobenzoic ester.

We hypothesised this 7,5-fused bicyclic lactam substructure 56 could be used to generate iminium salt catalyst 61 (Scheme 31), by the reduction of amide 56 to amine 62 and subsequent NBS induced iminium salt formation would give the desired iminium salt catalyst 61.
This methodology would allow almost any amino alcohol to be condensed within the biphenyl backbone. As demonstrated by Levacher, the condensation of \((R)\)-phenyl glycinal gives excellent diastereoisomeric and atropoisomeric control.

Furthermore either, enantiomer of the selected amino alcohol could be condensed within the biphenyl backbone so generating either enantiomer of the iminium salt catalyst (Scheme 32). Oxidation of the enantiopure iminium salt would generate, preferentially, one diastereoisomer of the oxaziridinium salt intermediate. This diastereoisomer of the
oxaziridinium salt in turn would then, preferentially, generate one enantiomer of the epoxide.

The synthesis of the desired bicyclic lactam was initiated using 2-iodo-benzoic acid (63) as our starting material; this was converted to the methyl ester, 64 with acetyl chloride in methanol (Scheme 33). The ethyl ester 65 was prepared by using thionyl chloride followed by potassium carbonate in ethanol (Scheme 33).

\[ \text{Reagents and conditions; (a) Acetyl chloride, MeOH, } \Delta \text{, 12 hrs. (b) Thionyl chloride, } \Delta \text{, 2 hrs. } K_2CO_3 \text{, absolute EtOH, } \Delta \text{, 12 hrs.} \]

\[ \text{Scheme 33} \]

The esters (64 & 65) underwent coupling with 2-acetylphenylboronic acid (60) using Suzuki methodology to yield the desired methyl and ethyl esters, 66 (Me) & 67 (Et).
The Suzuki conditions used by Levacher were a toluene:ethanol:water solvent system (10:1:1), potassium carbonate as the base (3 equiv.) and a palladium catalyst, specifically Pd(PPh₃)₄ (10 mol%), but we have observed similar yields when employing Pd(DPPF).

The reaction was heated under reflux over 48 h to give the biphenyl compounds in 64% (R = Me) and 76% (R = Et) yields.

The 2'-acetyl-biphenyl-2-carboxylic acid esters 66 (Me) & 67 (Et), underwent amino alcohol condensation with R-phenyl glycinol to generate the 7,5-fused bicyclic lactams with 95% de (R = Me) and 98% de (R = Et) as determined by ¹³C NMR spectroscopy (Scheme 35).

Reagents and conditions; (a) Toluene, EtOH, 5% aq. K₂CO₃, Pd(PPh₃)₄, Δ, 48 hrs.

Scheme 34

Reagents and conditions; (a) Toluene, Δ, (Me) 18 hr, (Et) 138 hr.

Scheme 35
The condensation generates the lactam as a pair of diastereoisomers with the major diastereoisomer 56 (aR,3R,13S based on CIP rules) generated in 86% yield displaying both functional groups of the oxazolidine moiety in a trans relationship (Scheme 36). Levacher describes this diastereoselectivity through $^1$H and $^{13}$C NMR spectroscopy. Our reported NMR spectroscopy data is in agreement with Levacher’s reported quotation.27

Levacher postulates that the trans-oxazolidine intermediate forms the lactam through a “pro-(aR) rotation” about the biaryl axis, giving rise to the exclusive formation of bicyclic lactam (aR,3R,13S) 56. Conformational restrictions in the 5,7-fused bicyclic lactam prevents the lactamisation of the trans-oxazolidine intermediate from taking place through a “pro-(aS) rotation” about the biaryl axis.27

![Scheme 36](image-url)
In contrast, the only way for the cis-oxazolidine intermediate to further react with the carboxylic acid or ester is to initiate a “pro-\((aS)\) rotation” about the biaryl axis to produce the \((aS,3R,13R)\) minor isomer 56. The absolute configuration of the chiral axis present in the biaryl unit was therefore controlled by that of the N,O-acetal centre in the oxazolidine intermediate.

With the desired single diastereoisomer of the 7,5-fused bicyclic lactam in hand, we endeavored to reduce the amide to the tertiary amine (Scheme 37, Table 11).

![Scheme 37](image)

Unfortunately the reduction of the amide did not occur using the reductive methodology shown. After aqueous work-up crude, \(^1\text{H}\) NMR spectroscopy showed no presence of the desired methylene protons, but more importantly the oxazolidine methyl group disappears, indicating decomposition of the starting material.
2.2.4 An alternative synthesis of 7,5-fused bicyclic azepinium salt catalysts.

Using Lavacher’s biphenyl lactam work as a synthetic guideline it was decided that an alternate route would be attempted in the absence of an amide group, hence removing the problematic reductive step.

We postulated that the tetracyclic amine 62 could be retrosynthetically disconnected to the biphenyl amino alcohol 69 (Scheme 38); this amino alcohol would be generated from oxazolidinone 70, which in turn would be prepared using Suzuki methodology from boronic acid 60 and oxazolidinone 71. Reductive amination of substituted oxazolidinone 72 with 2-iodobenzylbromide 73 would be used to initiate the synthesis.

\[ \text{Scheme 38} \]
Our first synthetic step was the alkylation of \((R)\)-phenyl oxazolidinone 72 with 2-iodobenzylbromide in 95% yield (Scheme 39).

\[
\begin{align*}

(d) HCl, TBME, Δ, 30 mins. (e) NBS, DCM, 0°C \(\rightarrow\) rt, 20 mins.

Scheme 39

The \(N\)-benzyl oxazolidinone 71 was coupled with acetyl phenyl boronic acid using Suzuki methodology described in the previous synthesis. The yield of this step was extremely poor when utilising Pd(PPh3)4 or Pd(DPPF) as the palladium catalyst within
several solvent systems (DMF, Tol:H₂O:EtOH, NMP, 1,4-dioxane) and base (K₂CO₃, KF, KOAc) combinations. With a difficult purification process also involved we therefore decided that the crude material would be taken on into the next synthetic step. Hydrolysis of the oxazolidinone was completed within aqueous sodium hydroxide in dichloromethane; the organic phase was immediately treated with p-TSA in methanol to generate the desired tetracyclic amine 62 in 10% yield over three steps. Finally the iminium bromide salt 61 was generated using NBS in chloroform.

We immediately tested iminium salt 61 for its catalytic ability (Scheme 40), using 1-phenylcyclohexene as our test substrate under our standard Oxone® oxidative conditions. Catalyst 61 gave 100% conversion within thirty minutes imparting a modest 55% ee for 1-phenylcyclohexene oxide.

\end{align*}
\]

\[
55\% \text{ ee} \\
100\% \text{ conv.}
\]

Scheme 40

From this result we had established a new group of iminium salt catalysts that was active for the catalytic asymmetric epoxidation of alkenes. Unfortunately the overall yield in this synthetic route tied with the problematic purification of many of the intermediates led us to seek another synthetic route.

We attributed the low yield of the second synthetic route to the presence of the oxazolidinone functionality. Both Suzuki methodology and oxazolidinone deprotection were thought to be sensitive procedures. The desired starting material and/or product are thought to degrade under one or both reaction conditions. We therefore decided to focus our attention on a synthetic intermediate that did not contain this problematic oxazolidinone.
Scheme 41

Scheme 41 shows our postulated retrosynthesis. The tetracyclic amine 62 would again be derived from a biphenyl backbone, but in this route the amino alcohol would be protected as the dimethyl acetal, 74. Disconnection with Suzuki methodology as before suggests the protected amino alcohol 75 as the precursor; this would be taken back through the iodobenzyl amino alcohol 76 and back to the starting materials, which we anticipated to be 2-iodobenzaldehyde (77) and phenyl glycinol (57).
It was decided that 2-Iodobenzaldehyde 77 would be generated within the laboratory, as it was not cost effective to purchase directly. Oxidation of 2-iodobenzyl alcohol 78 occurred with 85% yield (Scheme 42).

\[
\begin{align*}
\text{HO} & \quad \xrightarrow{\text{CHCl}_3, \text{MnO}_2, \Delta, 2 \text{ hrs.}} \quad \text{I} \\
78 & \quad \rightarrow \quad 77
\end{align*}
\]

Reagents and conditions; a. CHCl₃, MnO₂, Δ, 2 hrs.

Scheme 42

Lithium aluminium hydride was used to reduce (R)-Phenyl glycine 79, thus generating (R)-phenyl glycinol 57 retaining its enantiopurity as assigned by optical rotation (Scheme 43). Reductive amination of 2-iodobenzaldehyde with (R)-phenyl glycinol gave the N-benzyl amino alcohol 76 in 80% yield. Protection of the amino alcohol functionality with dimethoxypropane yielded the oxazolidine 75 in 91% yield.

The oxazolidine 75 was coupled with acetyl phenyl boronic acid 60 under what now were our ‘standard’ Suzuki conditions of a toluene:ethanol:water (10:1:1) solvent system, potassium carbonate base and catalysed by Pd(PPh₃)₄. Purification using column chromatography to isolate oxazolidine 74, gave two compounds by TLC. On closer inspection the acidic silica was deprotecting the dimethyl acetal, causing the molecule to ring close, generating the desired tetracyclic, 6,6,7,5 ring core 62. The reaction mixture was therefore treated with silica gel in chloroform over a 16-hour period. The reaction material was purified, giving the tertiary amine as a single diastereoisomer, the structure of which was absolutely defined by single X-ray analysis (Figure 80); this was smoothly converted to iminium salt 61 in 80% yield.
Reagents and conditions; (a) LAH, TMS-Cl, THF, $-78^\circ$C $\rightarrow$ rt, 2 hrs. (b) MeOH, NaBH$_3$CN, 0°C $\rightarrow$ rt, 16 hrs. (c) DMP, PhMe, pTSA, $\Delta$, 4 hrs. (d) PhMe:H$_2$O:EtOH, Pd(PPh$_3$)$_4$, aq. K$_2$CO$_3$, $\Delta$, 24 hrs. (e) Silica gel, CHCl$_3$, rt, 30 mins.

(f) NBS, CHCl$_3$, rt, 15 mins.

Scheme 43
Figure 80 An X-ray crystal of (R)-phenyl 6,6,7,5 tetracyclic tertiary amine

It was observed from Figure 80 that cyclisation of the amino alcohol functionality occurs placing the methyl and phenyl functionalities in a $c_{ts}$-relationship. Scheme 44 shows the mechanism of intramolecular cyclisation.

Scheme 44

On oxidation of the tertiary amines only one iminium proton is observed in the $^1$H NMR spectrum, therefore either, only one single atropoisomer is produced from the cyclisation step or, there is a rapid interconversion during the NMR time scale between the two possible atropoisomers favouring the more thermodynamically stable conformation when in the deuterated solvent. We also observe 95% diastereoselectivity in regard to the oxazolidine cyclisation.
Amino alcohol 76 was also tested for its activity under Suzuki methodology. What was expected was inactivation of the phosphorus catalyst leading to, at best, our unused starting material and no di-functionalised biphenyl backbone. To our delight, however, we achieved a one pot Suzuki coupling and intramolecular cyclisation generating the tetracyclic, 6,6,7,5 ring core (62) as one diastereoisomer in 40% yield in one step.

\end{align*}
\]

Scheme 45

From this route we were able to remove the protection and deprotection steps of the synthetic route, thus generating a new robust synthetic route with fewer steps, in which the phenyl substituted bromide azepinium iminium salt was generated in 24% yield over four steps.
Several analogues were then synthesised using (S)-alanine, (S)-valine, (R)- & (S)-phenylalanine and (1S,2R)-2-amino-1-phenyl-1-propanol (D-(-)-norephedrine). Catalysts 82, 83, 84, 85 and 86 were isolated as single diastereoisomers with the yields of the key steps in Table 12 and the overall yields indicated in parentheses.

</table>

\(^{a}\) epoxidation conditions: Iminium salt catalyst (5 mol%), Oxone® (2 equiv.), Na\(_2\)CO\(_3\) (4 equiv.), Solvent (1:1, Acetonitrile:H\(_2\)O 5 ml) 0°C, 1 hr – 6 hrs. \(^{b}\) Enantiomeric excesses were determined by chiral GC–FID spectra by comparison of the two epoxide peak areas. \(^{c}\) Conversions were evaluated from the chiral GC–FID spectra by comparison of the alkene and epoxide peak areas. \(^{d}\) Enantiomeric excess determined by Chiral HPLC on a Chiracel OH-D column. \(^{e}\) Conversions were evaluated from the \(^{1}\)H-NMR spectra by integration of alkene and epoxide signals. \(^{f}\) Absolute configurations of the major enantiomers were determined by comparison of both optical rotation and GC-FID.
From Table 13 it is evident that catalysts 61 (55%), 84 (64%) and 85 (64%) perform better when oxidising, 1-phenylcyclohexene, in terms of enantiocontrol, than catalysts 82, 83 and 86 (all give 30% ee). The enantioselectivities imparted to the test substrate are comparable to the original azepinium catalyst 7, which itself gives up to 60% ee. When other alkene substrates were tested in conjunction with these three catalysts, the enantiocontrol observed by each catalytic iminium salt was different, depending on the alkene substrate used. As a general rule the tetracyclic azepinium catalysts give similar or increased levels of enantioselectivity compared with catalyst 7. The best results are observed when oxidising a cis alkene such as dihydronaphthalene where catalysts 61 (76%), 84 (46%) and 85 (46%) outperform the original catalyst 7 (32%) considerably.

2.2.4.1 Conclusion

To conclude, we have successfully developed a new sub-structure of iminium salt catalyst containing a 6,6,7,5-ring tetracyclic core. The synthesis of these compounds has been streamlined and now the formulation of these novel iminium salts can be completed within four steps in good yields. We have postulated that the cyclisation occurs through one favoured atropoisomer giving rise to a favoured diastereoisomer in all the iminium salt catalysts generated. Catalysts 61, 84 and 85 generally perform better than or equal to catalyst 7.
2.3 Conclusion and Future work.

2.3.1 Conclusions

The aim of this thesis was the development of two novel ideas in the progression of catalytic asymmetric epoxidation. The first was the development of new oxidative systems for the use in asymmetric synthesis to induce higher levels of enantioselectivity for the epoxidation of unfunctionalised alkenes. The second was to develop chiral iminium salt catalysts with the ability to induce high levels of enantiocontrol in epoxidation of selected alkene substrates.

The new hydrogen peroxide-mediated epoxidation methodology offers modest enantiocontrol, up to 56% ee with the 7-membered azepine catalyst 7 that was capable of enantiocontrol up to 70% when using TPPP as the stoichiometric oxidant (Scheme 46). The major problem with the H₂O₂ system was the low levels of conversion to the desired epoxide.

The new sodium hypochlorite methodology offers much higher enantiocontrol and conversion when used in conjunction with the same azepinium catalyst over the H₂O₂ procedure, affording up to 71% ee (Scheme 47), similar to the enantioselectivities observed using TPPP as the oxidant. Comparison of the NaOCl system with Oxone® mediated epoxidation shows that the conversions are somewhat reduced.
Neither of these methods have ever previously been reported for oxidation of an iminium salt system. Optimisation has shown that lower reaction temperatures (–5 °C), anhydrous conditions, specific solvents and exchange of the sodium bicarbonate salt for potassium carbonate best facilitates asymmetric epoxidation when added in sub-stoichiometric amounts (0.25 equiv.), therefore acting as a co-catalyst in these systems.

Unfortunately due to the unstable nature of the binaphthalene based iminium salt catalyst in organic solvents, little conversion and ee was gained from these catalysts.

We have also developed two new sub-structures of biphenyl azepinium salt catalysts. The asymmetric introduction of a methyl substituent has been completed using an aminodioxane unit as a chiral element. In almost all cases, increased enantioselectivity was achieved by catalyst 40 compared with the parent catalyst 7 when used in conjunction with our standard Oxone® conditions.

Binaphthyl catalyst 52 was generated as a pair of diastereoisomers. When catalyst 52 was
used the mixture of diastereoisomeric salts gave up to 93% ee, marginally higher enantiocontrol in the epoxidation of 1-phenylcyclohexene over the parent catalyst 4 (91% ee).

The 6,6,7,5-ring tetracyclic azepinium salt catalysts show promise as a new form of iminium salt catalyst. Thus far the phenyl (61) and benzyl (84 & 85) substituted catalysts have given the best reaction profiles, giving increased enantioselectivity over the original azepinium catalyst 7. Further work is on going in this field.
2.3.2 Future Work

Thus far only binaphthyl iminium salt 52 has been generated with Grignard addition to the ‘mis-matched’ diastereoisomer of the binaphthyl iminium salt. A pair of diastereoisomers was generated as the conflicting asymmetry of the binaphthyl and dioxane moieties both direct the Grignard addition. If the Grignard addition were introduced to the matched diastereoisomer iminium salt, catalyst 98 could be generated. Asymmetric addition may be observed due to the matching asymmetry of the two functionalities, therefore possibly generating one diastereoisomer. In turn increased enantiocontrol in subsequent epoxidations may also be observed.

Optimisation of the 6,6,7,5 tetracyclic azepinium salt catalysts is suggested. This can be completed by investigation into the presence of multiple chiral groups $\alpha$ to both the iminium nitrogen and the oxygen atoms (R$_1$ and R$_2$, 99).

A progression of this is the variance of the substitution on the chiral carbon on the azepinium ring (R$_3$, 99). This range of optimisations would identify the most effective iminium salt in this sub-structure of catalyst.
Modification of the 6,6,7,5-ring tetracyclic azepinium salt catalysts to include a binaphthyl axis in place of the biphenyl axis is recommended. Increased enantiocontrol has been imparted by catalysts that contain this binaphthyl skeleton.

Again full variance on all ‘R’ groups would complete optimisation, identifying the most effective iminium salt in this sub-structure of iminium salt catalyst.

Construction of a 6,6,7,5-ring tetracyclic azepinium salt catalysts without the oxazolidine ring such as 101 and 102, would present an interesting comparison to the 6,6,7,5-ring tetracyclic azepinium salt catalyst that have already been synthesised.

Finally we need to investigate the mechanism by which our catalysts work. The use of computational and molecular modelling is possibly the best way to progress in aiding our research into explaining how our catalysts work. This approach may lead us to design more effective iminium salt catalysts capable of selecting one enantiotopic face in favour of the other, thus inducing higher enantiocontrol than our current catalysts.

Lygo, B.; Allbutt, B. Synlett 2004, 326.
Chapter Three: Experimental
3 Experimental

3.1 General experimental

Infrared spectra were acquired using a Perkin-Elmer Paragon 1000 FT-IR spectrophotometer. Solid samples were run as nujol mulls or as thin films of their solution in DCM on sodium chloride plates. Liquid samples were run neat.

$^1$H and $^{13}$C NMR spectra were measured at 400.13 and 100.62 MHz respectively using a Bruker DPX 400 MHz spectrometer and a Bruker Avance 400 MHz spectrometer. The solvent used for NMR spectroscopy was deuteriated chloroform (unless stated otherwise) using tetramethylsilane as the internal reference. Chemical shifts are given in parts per million (ppm) and $J$ values are given in Hertz (Hz).

Mass spectra were recorded using a Jeol-SX102 instrument utilising electron impact (E.I.) and fast atom bombardment (F.A.B.). Analysis by GCMS utilised a Fisons GC 8000 series (AS 800), using a 15 m x 0.25 mm DB-5 column and an electron impact low-resolution mass spectrometer.

Melting points were recorded using an Electrothermal-iA 9100 melting point instrument and are reported uncorrected.

Optical rotation values were measured with an Optical Activity-polAAar 2001 instrument, operating at $\lambda=589$ nm, corresponding to the sodium D line at the temperatures indicated. The solvents used for these measurements were of spectrophotometric grade. The solutions for these measurements were prepared in volumetric flasks for maximum accuracy of the volume of solvent used.

Microanalyses were performed on a Perkin Elmer Elemental Analyser 2400 CHN.
All chromatographic manipulations used silica gel as the adsorbent. Reactions were monitored using thin layer chromatography (TLC) on aluminium- or glass-backed plates with Merck Kiesel gel 60 F254 silica gel. TLC plates were visualised by UV radiation at a wavelength of 254 nm, or stained by exposure to an ethanolic solution of phosphomolybdic acid (acidified with concentrated sulphuric acid), followed by charring where appropriate. Purification by column chromatography used Merck Kiesel gel 60 F254 silica gel.

Reactions requiring anhydrous conditions were carried out under a nitrogen atmosphere unless otherwise stated, using glassware dried for 16 h at 150 °C. Reaction solvents were obtained commercially dry, except for the following light petroleum (b.p. 40-60 °C) was distilled from calcium chloride prior to use. Ethyl acetate was distilled over calcium sulphate or chloride. Dichloromethane was distilled over calcium hydride. Tetrahydrofuran was distilled under a nitrogen atmosphere from the sodium/benzophenone ketyl radical.

Enantiomeric excesses were determined by either chiral shift proton Nuclear Magnetic Resonance, Chiral Gas Chromatography Flame Ionisation (GC-FID), or by Chiral High Performance Liquid Chromatography, (Chiral HPLC).

The chiral shift proton nuclear magnetic resonance spectra were recorded in deuteriated chloroform on a Bruker DPX 400, operating at 400.13 MHz, in the presence of europium (III) tris [3-(hepta-floropropylhydroxymethylene)-(+)camphorate], [(+)-Eu(hfc)₃], as the chiral shift reagent and tetramethylsilane as the internal standard.

The chiral column used for the determination of enantiomeric excesses (ee) of non-racemic mixtures by chiral HPLC was Chiracel OD on a TSP Thermo-Separating-Products Spectra Series P200 instrument, with a TSP Spectra Series UV100 ultra-violet absorption detector set at 254 nm and a Chromojet integrator. Solvents used (hexane and isopropanol) were of HPLC grade.
The chiral column used for the determination of enantiomeric excesses (ee) of non-racemic mixtures by chiral GC-FID was Chiradex B-DM on a CE instruments GC 8000 series spectrometer, with flame ionisation detector and a Chrome-card integrator. The solvent used (hexane) was of HPLC grade.

3.2 Numbering systems.

The assignments of the proton and carbon-13 resonances have been made according to several numbering systems (Scheme 1). Some of these systems used are standard chemical nomenclature while others were introduced arbitrarily by a previous author. In the latter case, the introduced system was based on the structural resemblance of the compounds to others in the literature.

Aromatic systems are numbered according to standard protocols. Aromatic carbon atoms bearing a substituent are always quaternary, quat.Ar-C. All aromatic carbon atoms which are attached to a hydrogen atom are termed Ar-CH ($^{13}$C spectra) or Ar-CH ($^1$H spectra).

The dihydroisoquinolinium nucleus is numbered according to a standard system but the carbon atoms of this moiety are termed isoq. The biphenyl system is also numbered and carbon atoms of this moiety are termed biphenyl. The binapthylenyl nucleus is numbered with the carbon atoms termed binap.

Scheme 1 Numbering systems employed in the experimental procedures.
3.3 Individual experimental procedures

\[(3S,4S)-N-(2,2-Dimethyl-4-phenyl-(1,3)dioxan-5-yl)-formamide.\]

\[8\] - 2-Aminophenyl-1,3-propanediol (5.00 g, 29.9 mmol) was dissolved in methanol (50.0 mL), methyl formate (2.00 g, 32.9 mmol) was added followed by an aqueous solution of sodium methoxide (25% w/v, 2.03 mL, 3.00 mmol). The reaction was monitored by TLC until complete consumption of the starting material was observed (typically 2 h). The resulting solution was evaporated under reduced pressure to afford the formyl-protected amine (9) as a yellow oil. The oil was dissolved in acetone (250 mL), and 2,2-dimethoxypropane (31.1 g, 3.00 mol) and aqueous hydrogen bromide (48%, 0.34 mL, 3.00 mmol) were added. The reaction was monitored by TLC until consumption of the intermediate compound was observed (typically 1.5 h). The solvents were removed under reduced pressure to give the crude formyl-protected acetonide (10) as a colourless oil (6.58 g, 29.1 mmol, 97%).

\[\nu_{\text{max}}(\text{film}) / \text{cm}^{-1} \quad 3325 \text{ (N-H)}, 2990, 1663 \text{ (C=O)}, 1499, 1382, 1200, 1087, 844, 733, 700. \delta_H (400 \text{ MHz; CDCl}_3) 1.49 \text{ (3 H, s, C}_8\text{H}_3), 1.53 \text{ (3 H, s, C}_7\text{H}_3), 3.35 \text{ (1 H, s, NC}_5\text{H}), 3.81 \text{ (1 H, m, OC}_6\text{H}_2), 5.16 \text{ (1 H, s, PhC}_4\text{H}), 6.48 \text{ (1 H, broad s, NH)}, 7.27 \text{ (5 H, m, 5 x Ar-C}_10\text{H}_4\text{)}, 7.88 \text{ (1 H, s, NC}_15\text{O)}, 8.98 \text{ (quat.C}_2\text{)}, 124.2 \text{ (2 x ortho Ar-C}_10\text{H}_4\text{)}, 126.6 \text{ (para Ar-C}_12\text{H}_4\text{)}, 127.3 \text{ (2 x meta Ar-C}_11\text{H}_13\text{)}, 137.0 \text{ (Ar-quat.C}_2\text{)}, 159.5 \text{ (C}_15=\text{O)}\]
Formamide 10 (6.58 g, 28.1 mmol) was suspended in an 85% saturated aqueous solution of hydrazine hydrate (100 mL) and the mixture heated under reflux for 4 h. The reaction mixture was extracted with toluene and ethyl acetate (1:1, 75 mL), and the combined organic layers were washed with water (3 x 75 mL) and dried over MgSO₄. The solvents were removed under reduced pressure to give the desired amine as a yellow oil (11) (5.39 g, 87% yield). \([\alpha]_{D}^{20} +45.5^\circ \) (c 2.33, EtOH). \(\nu_{\text{max}}\) (film) /cm\(^{-1}\) 3365 (N-H), 2990, 1379, 1239, 1159, 1052, 945, 845, 740, 701. \(\delta_{H}\) (400 MHz; CDCl\(_3\)) 1.44 (6 H, s, 2 x C\(^7\&8\)H\(_3\)), 2.64 (1 H, q, J 1.8 Hz, NC\(^5\)H), 3.78 (1 H, dd, J 1.7 & 11.7 Hz, OC\(^6\)H\(_2\)), 4.18 (1 H, dd, J 2.3 & 11.7 Hz, OC\(^6\)H\(_2\)), 4.99 (1 H, s, PhC\(^4\)H), 7.23 (5 H, m, 5 x Ar-C\(^{10-14}\)H). \(\delta_{C}\) (100 MHz; CDCl\(_3\)) 18.6 (C\(^8\)H\(_3\)), 29.7 (C\(^7\)H\(_3\)), 49.6 (NC\(^5\)H), 65.9 (OC\(^6\)H\(_2\)), 73.7 (PhC\(^4\)H), 99.1 (quat.C\(^2\)), 125.9 (2 x ortho Ar-C\(^{10\&14}\)H), 127.4 (para Ar-C\(^{12}\)H), 128.4 (2 x meta Ar-C\(^{11\&13}\)H), 139.8 (Ar-quat.C\(^0\)).
Bromine (3.24 mL, 63.1 mmol) was added slowly to an ice-cooled solution of isochroman (12) (7.70 g, 57.4 mmol) in carbon tetrachloride (10 mL) over a period of 10 min with stirring. After the exothermic reaction subsided, the cooling bath was removed and the dark brown solution heated under reflux until the reaction mixture became pale yellow and liberation of HBr fumes ceased (typically 1.5 h). The solution was allowed to attain ambient temperature temperature and the solvent removed under reduced pressure. A 48% saturated aqueous solution of hydrobromic acid (50 mL) was added to the yellow oil obtained (1-bromoisochroman), and the reaction mixture heated under reflux. After 15 min the solution was allowed to cool and extracted with diethyl ether (4 x 50 mL). The combined organic extracts were washed with water (2 x 30 mL) and saturated aqueous sodium bicarbonate, and dried over magnesium sulfate. Evaporation of the solvent under reduced pressure furnished crude 2-(2-bromo-ethyl)benzaldehyde (13) as an orange oil; about 85 – 90% pure (5.30 g, 43%). Analytically pure samples could be obtained by distillation under reduced pressure; chromatography is not recommended. Both the crude and the distilled compound can be used in the synthesis of dihydroisoquinolinium salts. Found: C, 50.95; H, 4.20%; C₉H₈BrO requires C, 50.73; H, 4.26 %. ν max/cm⁻¹ (neat) 2742, 1697 (C=O), 1600, 1575, 1260, 1193, 755. δ H (400 MHz; CDCl₃), 3.50 (4 H, m, Ph(C₇H₂)₂Br), 7.24 (1 H, td, J 6.96 & 0.5 Hz, Ar-H), 7.39 (1 H, dt, J 8.8 & 1.3 Hz, Ar-CH), 7.47 (1 H, dt, J 9.1 & 1.6 Hz, Ar-CH), 7.73 (1 H, dd, J 1.6 & 7.6 Hz, Ar-CH) 10.05 (1 H, s, C₂H₂O). δ C (100 MHz; CDCl₃), 32.8 (PhC₇H₂), 36.3 (BrC₈H₂), 127.7 (Ar-CH), 132.2 (Ar-CH), 133.7 (Ar-CH), 134.6 (Ar-CH), 140.6 (2xquat.Ar-1C₁&₂), 193.0 (C₂H₂O).

Method A

To an ice cooled solution of carbaldehyde \(\textbf{99}\) (3.30 g, 12.0 mmol) in ethanol (35 mL), a solution of amine \(\textbf{11}\) (2.05 g, 7.00 mmol) in ethanol (20 mL) was added and left to heat to ambient temperature for 16 h. Sodium tetraphenylborate (3.76 g, 12.0 mmol) was dissolved in the minimal amount of acetonitrile (approximately 5 mL). This was then added to the reaction mixture and after 5 min gave a yellow precipitate. Ethanol and water were added to the reaction mixture. The mixture was then filtered, washed with cold ethyl acetate (3 x 10 mL), cold water (1 x 10 mL) and diethyl ether (3 x 10 mL) yielding the desired azepinium tetraphenyl borate salt (7) as a yellow powder.
Method B

N-((4S,5S)-2,2-Dimethyl-4-(4-(methylsulfanyl)-phenyl)-1,3-dioxan-5-yl)formamide.⁷

Thiomicamine (17) (10.0 g, 46.9 mmol.) was dissolved in methanol (100 mL), and methyl formate (3.20 mL, 51.4 mmol) added followed by a methanoic aqueous solution of sodium methoxide (25% w/v, 1.08 mL, 4.70 mmol). The reaction was monitored by TLC until complete consumption of the starting material was observed (typically 2 h). The resulting solution was evaporated under reduced pressure to afford the formyl-protected amine 18 as a yellow oil. The oil was dissolved in acetone (500 mL), 2,2-dimethoxypropane (57.6 mL, 0.469 mol) and p-TSA (0.89 g, 4.70 mmol) were added. The reaction was monitored by TLC until consumption of the intermediate product was observed (typically 1.5 h). The solvents were removed under reduced pressure and the residue re-dissolved in ethyl acetate (100 mL), which underwent saturated aqueous work up with saturated aqueous NaHCO₃ (3 x 60 mL). The organics were dried over MgSO₄ and solvents removed under reduced pressure affording acetonide 19 (13.2 g, 46.9 mmol,

(+)-(4S,5S)-2,2-Dimethyl-4-(4-(methylsulfonyl)-phenyl)-1,3-dioxan-5-yl)-3,4-dihydroisoquinolinium tetraphenylborate.\(^7\)

A solution of amine \(21\) (3.53 g, 12.4 mmol) in ethanol (70 mL) was added dropwise to 2-(2-bromoethyl)benzaldehyde (\(13\)) (3.17 g, 14.9 mmol) at 0 °C. The reaction mixture was stirred for 16 h while reaching ambient temperature. Sodium tetraphenylborate (5.10 g, 14.9 mmol) in the minimum amount of acetonitrile (approximately 5 mL) was added in 1 portion to the reaction mixture, and after stirring for 5 min the organic solvents were removed under reduced pressure. Ethanol was added to the reaction mixture followed by water followed by diethyl ether. Washing and filtration with ethanol and diethyl ether yielded the desired tetraphenyl borate salt, \(1\), as a yellow powder (0.35 g, 0.50 mmol, 35%). (R)-Trifluoro-methanesulfonic acid 2'-trifluoromethanesulfonyloxy (1,1')binaphthalenyl-2-yl ester.8

(R)-[1,1']Binaphthalenyl-2,2'-diol (45) (3.40 g, 11.8 mmol) was dissolved in dichloromethane (40.0 mL) and cooled to −30 °C. To this was added 4-dimethylaminopyridine (0.58 g, 4.72 mmol), 2,6-lutidine (3.80 mL, 35.5 mmol) and triflic anhydride (5.97 mL, 35.5 mmol). The solution was allowed to warm to ambient temperature and stirred for 4 h. Silica gel was added to the solution and the solvent evaporated under reduced pressure. The compound, adsorbed on silica, was transferred to a fritted glass funnel and washed with ethyl acetate/light petroleum until the title compound had eluted. Solvents were removed under reduced pressure to yield a crude colourless solid, which was recrystallized from hexane to give colourless crystals (46) (5.39 g, 9.23 mmol, 99%). Lit.9 mp 82 – 85 °C, mp 76 – 78 °C. ν_{max}(film) /cm^{-1} 1419, 1215, 1139 (S-O), 1065 (S=O), 1030 (S=O), 962, 940, 830. [α]^{20}_{D} −140 ° (c 1.06, CHCl₃). \((R)-(4S,5S)-2,2\text{-dimethyl-4-phenyl-1,3-dioxan-5-yl)-3 H-4-azapinium-cyclohepta(2,1-a;3,4-a')dinaphthalene tetraphenylborate}\.^8

Method A

To an ice cooled solution of \((R)-2'\)-Bromomethyl-[1,1']binaphthalenyl-2-carbaldehyde (106) (0.72 g, 1.91 mmol) in ethanol (8 mL), a solution of amine 11 (0.38 g, 1.84 mmol)
in ethanol (5 mL) was added and allowed to warm to ambient temperature over 16 h. Sodium tetraphenylborate (0.69 g, 1.91 mmol) was dissolved in the minimal amount of acetonitrile (approximately 5 mL). This solution was subsequently added to the reaction mixture and, after approximately 5 min, gave a yellow precipitate. Ethanol, followed by water, was then added to the reaction mixture. The mixture was then filtered, washed with cold ethanol, cold water and diethyl ether giving the desired yellow crystals (3) (1.01 g, 1.25 mmol, 68%).

Method B

\[ \text{N-Bromosuccinimide (0.35 g, 1.95 mmol) was added to a solution of amine 49 (0.87 g, 1.77 mmol) in CHCl}_3 (10 \text{ mL}). \text{The reaction was stirred under reflux for 5 min. The solution was cooled to ambient temperature and extracted from water (3 x 50 mL), saturated brine (3 x 50 mL) and dried over MgSO}_4. \text{The solvent was removed under reduced pressure, the resulting yellow foam was dissolved in ethanol and cooled to 0 °C. Sodium tetrphenylborate (0.86 g, 2.5 mmol) was dissolved in the minimal amount of acetonitrile (approximately 5 mL), this solution was subsequently added to the reaction mixture and allowed to warm to ambient temperature to give a yellow precipitate. Ethanol followed by water was added to the reaction mixture. The mixture was then filtered, washed with cold ethanol, cold water and diethyl ether giving the desired yellow crystals (3) (0.68 g, 1.2 mmol, 68%).} \]

6-(2,2-Dimethyl-4-phenyl-(1,3)dioxan-5-yl)-dibenzo-(c,e)-azepine-5,7-dione.

Diphenic acid (107) (0.50 g, 2.10 mmol) was added to a solution of the acetonide (11) (0.43 g, 2.10 mmol) in chloroform (10 mL). The solution was heated under reflux for 3 h. The solution was then allowed to cool down to ambient temperature and the solvent was removed under reduced pressure. The crude reaction mixture was dissolved in a saturated aqueous solution of NaSO₄ (5 mL) in acetic anhydride (50 mL) and was heated under reflux for 30 min, hot water was then added. The solution was allowed to cool down to ambient temperature, the crude compound was then extracted with DCM (3 x 20 mL), the combined organic phases were dried over MgSO₄ and the solvent was removed under reduced pressure. The resulting dark yellow powder was re-crystallized from methanol to yield the desired imide as a yellow powder (108) (0.71 g, 1.70 mmol, 81%).

General procedure for the addition of Grignard reagents to biphenyl azepinium salts.

The desired azepinium salt (1 equiv) was dissolved in anhydrous THF (30 mL per g) under nitrogen and cooled to $-78 \, ^\circ\text{C}$. The desired Grignard reagent (3 equiv) was added dropwise over 5 min to the cold solution. The reaction was then allowed to warm to ambient temperature and stirred for 2 h. The reaction was then cooled to 0 °C and quenched with Rochelle’s salt. The reaction was allowed to warm to ambient temperature where it was extracted with water, saturated brine and dried over MgSO₄. The solution was filtered and silica was added, the solvent was removed under reduced pressure. The crude reaction mixture was purified via column chromatography using 1:99 (ethyl acetate/petrol) to yield the desired amine.

General procedure for the synthesis of biphenyl azepinium bromide salts from heterocyclic amines and $N$-bromosuccinimide.

To a solution of the desired amine (1 equiv) in DCM (15 mL g of amine) was added $N$-bromosuccinimide (1.1 equiv) in DCM (15 mL per g of NBS) and the reaction mixture was refluxed for 2 h. The reaction was cooled to ambient temperature when it was then extracted with water, saturated brine and dried over MgSO₄. The solvent was removed under reduced pressure to yield the crude bromide iminium salt. Recrystallisation from diethyl ether gave the purified biphenyl azepinium bromide salt.
General procedure for the synthesis of biphenyl azepinium tetraphenylborate salts from biphenyl azepinium bromide salts.

To a ice cooled solution of the desired biphenyl azepinium salt (1 equiv) in DCM was added sodium tetraphenylborate (1.2 equiv) dissolved in the minimal amount of acetonitrile (approximately 5 mL). The reaction mixture was stirred whilst attaining ambient temperature over 10 min forming a yellow precipitate. The precipitate was filtered, washed with cold ethanol, cold water and diethyl ether to yield the desired yellow crystals.

5-Methyl-6-(2,6,6-trimethyl-bicyclo(3.1.1)hept-3-yl)-6,7-dihydro-5H-dibenzo-(c,e)-azepine.

Prepared according to the general procedure from (+)-6-[(1R,2R,3R,5S)-2,6,6-trimethylbicyclo[3.1.1]hept-3-yl]-5H-dibenzo[c,e]azepinium tetraphenylborate (30) (0.50 g, 0.77 mmol) and methyl magnesium bromide (0.28 mL, 0.85 mmol). The purified amine was isolated as a colourless oil, as a pair of diastereoisomers (33) (0.16 g, 0.61 mmol, 79%). $\nu_{\text{max (film)}}$ /cm$^{-1}$ 3057, 3054, 2923, 2359, 2339, 1627, 1596, 1558, 1472, 1448, 1424, 1387, 1261, 1091, 1031, 799, 734, 703, 667. $\alpha_D^{20}$ +81.3 ° (c 0.30,

4-(2,2-Dimethyl-4-phenyl-(1,3)dioxan-5-yl)-3-methyl-3$H$-4-azonia-cyclohepta(2,1-$a$;3,4-$a'$)dinaphthalene; Bromide salt.

Prepared according to the general procedure from amine 51 (0.34 g, 0.66 mmol) and NBS (0.24 g, 1.33 mmol) to yield the desired binaphthalene azepinium salt catalyst 52 As a dark yellow powder (0.30 g, 0.52 mmol, 79%). $\nu_{\text{max}}$(film) /cm$^{-1}$ 3392, 2359, 1695, 1377, 1190, 1112, 820, 753, 667. $[\alpha]_{D}^{20}$ = 96.4° (c 0.71, CHCl$_3$). $\delta$H (400 MHz; CDCl$_3$) 1.05 (3 H, d, $J$ 7.2 Hz, NCH(C$_{11}$H$_3$)), 1.70 (6 H, s, 2 x C$_7$&8H$_3$), 4.34 (1 H, d, $J$ 14.0 Hz, upfield portion of ABX system, OC$_6$H$_2$), 4.97 (1 H. dd, J 2.4 & 14.0 Hz, downfield portion of ABX system, OC$_6$HH), 5.41 (1 H, s (broad), NC$_5$H), 5.72 (1 H. d, J 2.0 Hz, OC$_4$HPh), 5.98 – 6.08 (1 H, m, NC$_{10}$H(CH$_3$), 6.74 (1 H, d, J 9.2 Hz, Ar-CH$_3$), 7.05 – 7.16 (3 H. m, 3 x Ar-CH$_3$), 7.24 – 7.36 (3 H. m, 3 x Ar-CH$_3$), 7.37 – 7.50 (3 H, m, 3 x Ar-CH$_3$), 7.54 – 7.67 (3 H. m, 3 x Ar-CH$_3$), 7.86 (1 H. d, J 8.0 Hz, Ar-CH$_3$), 7.94 (2 H. dd, J 8.4 & 10.8 Hz, 2 x Ar-CH$_3$), 8.05 (1 H. d, J 8.4 Hz, Ar-CH$_3$), 9.54 (1 H, s, N=CH). $\delta$C (100 MHz; CHCl$_3$) 18.7 (C$_{11}$H$_3$), 29.8 (C$_7$ or 8H$_3$), 31.0 (C$_7$ or 8H$_3$), 62.5 (OC$_6$H$_2$), 67.1 (CH), 67.9 (CH), 71.2 (CH), 101.0 (quat.Ar-C$^2$H), 124.5 (Ar-CH$_3$), 124.6 (Ar-CH$_3$), 125.5 (Ar-CH), 126.8 (Ar-CH)$_2$, 127.4 (Ar-CH)$_2$, 128.01 (Ar-CH)$_2$, 128.06 (Ar-CH)$_2$, 128.2 (Ar-CH), 128.3 (Ar-CH), 128.5 (Ar-CH), 129.3 (Ar-CH), 129.7 (Ar-CH), 130.8 (Ar-CH), 132.2 (Ar-CH), 134.7 (quat.Ar-C), 135.4 (quat.Ar-C), 136.9 (quat.Ar-C), 137.1 (quat.Ar-C), 137.6 (quat.Ar-C), 139.4 (quat.Ar-C), 141.2 (quat.Ar-C), 142.6 (quat.Ar-C), 169.2 (quat.Ar-C), 177.4 (N=CH). m/z 498.24435 [+ 1.9 ppm]; C$_{35}$H$_{32}$NO$_2$Br requires 498.24331.
Acetyl chloride (0.31 mL, 4.40 mmol) was added to a solution of 2-iodobenzoic acid (63) (1.00 g, 4.00 mmol) in methanol (50 mL). The reaction mixture was heated under reflux for 16 h. The reaction was allowed to cool to ambient temperature. The crude product was extracted from saturated aqueous hydrochloric acid (2 x 50 mL, 1 M), and saturated brine (2 x 50 mL), and dried over MgSO₄. The solvent was removed under reduced pressure to yield the desired product (64) as a yellow oil (0.84 g, 3.20 mmol, 81%).

ν<sub>max</sub>(film) /cm<sup>-1</sup> 1726, 1284, 1254, 1130, 1107, 1014, 743. δ<sub>H</sub> (400 MHz; CDCl<sub>3</sub>) 3.85 (3 H, s, OCH₃), 7.06 (1 H, dt, <i>J</i> 8.0 & 2.0 Hz, Ar-C<sup>2</sup>H<sub>ortho</sub> to ester group), 7.31 (1 H, dt, <i>J</i> 1.2 & 7.6 Hz, Ar-C<sup>2</sup>H<sub>meta</sub> to ester group, <i>ortho</i> to iodo group), 7.72 (1 H, dd, <i>J</i> 1.6 & 8.0 Hz, Ar-C<sup>3</sup>H<sub>para</sub> to ester group, <i>ortho</i> to iodo group), 7.90 (1 H, dd, <i>J</i> 1.2 & 8.0 Hz, Ar-C<sup>4</sup>H<sub>meta</sub> to ester group, <i>para</i> to iodo group). δ<sub>C</sub> (100 MHz; CDCl<sub>3</sub>) 14.6 (OCH₃), 94.3 (quat.C<sup>1</sup> ipso to iodo group), 128.2 (Ar-CH), 131.2 (Ar-CH), 132.8 (Ar-CH), 135.8 (quat.C<sup>6</sup> ipso to ether), 141.6 (Ar-CH), 167.0 (quat.C=O).
A solution of 2-iodobenzoic acid (63) (1.00 g, 4.00 mmol) in thionyl chloride (10 mL, 142 mmol) was heated under reflux for 2 h. The reaction was allowed to cool to ambient temperature and the solvent removed under reduced pressure. The crude intermediate was dissolved in absolute ethanol (14 mL) and heated under reflux for 12 h. The reaction was allowed to cool to ambient temperature. The solvent was removed under reduced pressure and the residue dissolved in 5% saturated aqueous potassium carbonate solution. The organic phase was extracted into DCM and dried over MgSO₄. The solvent was removed under reduced pressure to yield the desired ester as a yellow oil (65).

ν\text{max}(\text{film}) /\text{cm}^{-1} 1724, 1285, 1255, 1133, 1102, 1015, 741. δ\text{H} (400 MHz; CDCl₃) 1.33 (3 H, dt, \text{J} 6.8 \& 2.4 Hz, OCH₂C₈H₃), 4.32 (2 H, dq, \text{J} 7.2 \& 2.8 Hz, OC₈H₂CH₃), 7.05 (1 H, t, \text{J} 7.2 Hz, Ar-C₅H ortho to ester group), 7.31 (1 H, t, \text{J} 7.6 Hz, Ar-C²H meta to ester, ortho to iodo group), 7.70 (1 H, d, \text{J} 7.6 Hz, Ar-C₃H para to ester), 7.89 (1 H, d, \text{J} 8.0 Hz, Ar-C⁴H meta to ester, para to iodo group). δ\text{C} (100 MHz; CDCl₃) 14.3 (C₈H₃), 61.7 (OC₈H₂), 94.0 (quat.C₁ ipso to iodo), 127.9 (Ar-CH), 130.8 (Ar-CH), 132.5 (Ar-CH), 135.4 (quat.C⁶ ipso to ether), 141.2 (Ar-CH), 166.6 (quat.C=O).
Acetyl phenyl boronic acid (50) (0.53 g, 3.20 mmol) and saturated aqueous potassium carbonate (1.32 g, 9.40 mmol) were added to a solution of 2-iodo-benzoic acid methyl ester (64) (0.93 g, 3.40 mmol) in toluene (50 mL), ethanol (5 mL) and water (6 mL). The reaction mixture was degassed with a nitrogen flow over 30 min. After adding Pd(PPh₃)₄ (185 mg, 0.16 mmol) the reaction mixture was degassed under a nitrogen flow over 15 min. The mixture was stirred under reflux and a nitrogen atmosphere for 24 h and allowed to cool to ambient temperature. The reaction mixture was then filtered through a plug of celite and the organic solvents were removed under reduced pressure and the crude reaction mixture was dissolved in diethyl ether (50 mL). The combined organic layers were washed with water (2 x 40 mL) and dried over MgSO₄. The solvents were removed under reduced pressure, and the crude compound was purified by flash chromatography (ethyl acetate/petrol 15% − 100%) to afford the desired biaryl compound as a yellow oil (66) (0.66 g, 2.6 mmol, 76%). \( \nu_{\text{max}} \) (film) / cm⁻¹: 2949, 1725, 1688, 1289, 1127, 1091, 761. \( \delta_{\text{H}} \) (400 MHz; CDCl₃) 2.08 (3 H, d, \( J = 0.8 \) Hz, OC₉H₃), 3.53 (3 H, d, \( J = 0.4 \) Hz, COC₈H₃), 7.06 (1 H, ddd, \( J = 0.4, 0.8 \) & 7.2 Hz, Ar-CH), 7.10 (1 H, ddd, \( J = 0.4, 0.8 \) & 7.6 Hz, Ar-CH), 7.293 − 7.432 (4 H, m, Ar-CH), 7.62 (1 H, ddd, \( J = 0.4, 0.8 \) & 7.6 Hz, Ar-CH), 7.88 (1 H, ddd, \( J = 0.4, 0.8 \) & 7.6 Hz, Ar-CH). \( \delta_{\text{C}} \) (100 MHz; CDCl₃) 29.4 (OC₉H₃), 52.0 (COC₈H₃), 127.4 (Ar-CH), 127.6 (Ar-CH), 128.2 (Ar-CH), 129.6 (quat.Ar-C), 130.2 (Ar-CH), 130.8 (Ar-CH), 130.9 (Ar-CH), 131.7 (Ar-CH), 138.7 (Ar-CH), 138.7 (quat.Ar-C), 140.9 (quat.Ar-C), 142.8 (quat.Ar-C), 167.5 (quat.Ar-C), 201.7 (quat.Ar-C).
2'-Formyl-biphenyl-2-carboxylic acid ethyl ester.\(^{14}\)

\[
\text{Acetyl phenyl boronic acid (60) (0.56 g, 3.4 mmol) and saturated aqueous potassium carbonate (1.4 g, 10 mmol) were added to a solution of 2-iodo-benzoic acid ethyl ester (65) (0.93 g, 3.4 mmol) in toluene (50 mL), ethanol (5 mL) and water (6 mL). 2'-Formyl-biphenyl-2-carboxylic acid methyl ester (66) (0.66 g, 2.60 mmol) [or 2'-formyl-biphenyl-2-carboxylic acid ethyl ester (67) (0.70 g, 2.60 mmol)] and R-phenylglycinol (57) (0.37 g, 2.60 mmol) were dissolved in toluene (13 mL) in a Dean-Stark apparatus. The mixture was stirred at reflux for 16 h. The reaction was allowed to cool to ambient temperature and solvent was removed under reduced pressure. The crude product was purified by flash chromatography on silica gel (ethyl acetate/petrol 10 – 25%) to provide the desired lactam (56) as a colourless oil, as a pair of diastereoisomers (0.39 g, 1.16 mmol, 57%). \(\nu_{\text{max}}(\text{film}) / \text{cm}^{-1}\) 3061, 2986, 2935, 2877, 1634, 1449, 1396, 1239, 1038, 743, 697. \(\alpha\)\(^{20}\)\(_D\) +108 ° (c 1.00, CHCl\(_3\)). \(\delta\)\(_{\text{H}}\) (400 MHz; CDCl\(_3\)) 1.45 (3 H, s, \(\text{C}_6\text{H}_3\)), 4.18 (1 H, dd, \(J\) 1.2 & 8.8 Hz, upfield portion of \(ABX\) system, OC\(^3\)H\(_3\)), 4.32 (1 H, q, \(J\) 6.0 Hz, downfield portion of \(ABX\) system, OC\(^3\)H\(_3\)), 5.36 (1 H, d, \(J\) 6.0 Hz, NC\(^2\)HPh), 7.22 (1 H, dd, \(J\) 1.2 & 14.8 Hz. \(\text{Ar-CH}\)), 7.28 – 7.51 (10 H, m, \(\text{Ar-CH}\)), 7.58 – 7.60 (1 H, m, \(\text{Ar-CH}\)), 7.80 (1 H, d, 1.2 & 7.6 Hz, \(\text{Ar-CH}\)). \(\delta\)\(_{\text{C}}\) (100 MHz; CDCl\(_3\)) 25.7 (\(\text{C}^6\text{H}_3\)), 61.8 (NC\(^2\)HPh), 71.0 (O\(^3\)H\(^3\)), 93.9 (quat.C\(^5\)OCH\(_3\)), 122.3 (Ar-\(\text{CH}\)), 126.9 (2 x Ar-\(\text{CH}\)), 127.6 (Ar-\(\text{CH}\)), 128.1 (Ar-\(\text{CH}\)), 128.3 (Ar-\(\text{CH}\)), 128.6 (2 x Ar-\(\text{CH}\)), 128.8 (Ar-\(\text{CH}\)), 128.9 (Ar-\(\text{CH}\)), 130.4 (Ar-\(\text{CH}\)), 130.8 (Ar-\(\text{CH}\)), 131.3 (Ar-\(\text{CH}\)), 133.4 (quat.C), 135.9 (quat.C), 137.2 (quat.C), 141.0 (quat.C), 142.0 (quat.C), 165.6 (quat.C\(^{13}\)O).
3-(2-iodo-benzyl)-4-phenyl-oxazolidin-2-one.

\[
\text{Br} \quad \text{HN} \quad \text{O} \\
\text{O} \quad \text{I} \quad \text{N} \quad \text{O} \\
\]

Method A

To a solution of \(R\)-(-)-4-phenyl-2-oxazolidinone (72) (0.20 g, 1.23 mmol) in THF (2 mL) at ambient temperature under a nitrogen atmosphere was added NaHMDS (2M in THF, 0.68 mL, 1.35 mmol) in one portion. After 30 min a solution of 2-iodobenzylbromide (73) (0.40 g, 1.35 mmol) in THF (2 mL) was added, the reaction mixture was heated to 50 °C and monitored by HPLC for completion. The reaction was allowed to cool to ambient temperature at which point saturated potassium carbonate and TBME were added. The organic fraction was separated and dried over magnesium sulphate. The solvent was removed under reduced pressure to yield the desired alkylated oxazolidinone as a low melting solid (71) (0.46 g, 1.21 mmol, 98%).

Method B

To a solution of \(R\)-(-)-4-phenyl-2-oxazolidinone (72) (0.54 g, 3.36 mmol) in THF (5 mL) at ambient temperature under a nitrogen atmosphere was added potassium butoxide (12% in THF, 3.27 g, 29.1 mmol) in one portion. After 30 min a solution of 2-iodobenzylbromide (73) (0.80 g, 3.37 mmol) in THF (5 mL) was added, the reaction
mixture was heated to 50 °C and monitored by HPLC for completion. The reaction was allowed to cool to ambient temperature at which point saturated potassium carbonate and TBME were added. The organic fraction was dried over magnesium sulphate and the solvent was removed under reduced pressure to yield the desired alkylated oxazolidinone as a low melting solid (71) (1.13 g, 2.99 mmol, 89%). \( v_{\text{max}}(\text{film}) / \text{cm}^{-1} \) 2960, 1749, 1428, 1240, 1081, 1012, 751, 668. \( \alpha^D \) \( -56.0 \) ° (c 0.65, CHCl\(_3\)), \( \delta_H \) (400 MHz; CDCl\(_3\)) 4.00 (1 H, d, \( J \) 16.0 Hz, NCH\(_2\)), 4.18 (1 H, dd. \( J \) 8.0 & 12.0 Hz, NCHPh), 4.57 (1 H, dd, \( J \) 4.0 & 12.0 Hz, OCHH), 4.63 (1 H, t, \( J \) 8.0 Hz, OCHH), 4.79 (1 H, d, \( J \) 16.0 Hz, OCHH), 6.97 (1 H, t, \( J \) 8.0 Ar-CH), 7.15 – 7.19 (3 H, m, 3 x Ar-CH), 7.26 – 7.30 (1 H, m, Ar-CH), 7.34 – 7.41 (3 H, m, 3 x Ar-CH), 7.79 (1 H, d, \( J \) 8.0 Hz, Ar-CH). \( \delta_C \) (100 MHz; CHCl\(_3\)) 51.1 (OC\(_2\)H), 59.7 (NC\(_2\)H), 70.5 (NCH\(_2\)), 99.3 (quat.Ar-C, ipso in iodopenyl ring), 114.4 (Ar-C\(_{CH}\)), 126.6 (Ar-C\(_{CH}\)), 127.6 (Ar-C\(_{CH}\)), 129.0 (Ar-C\(_{CH}\)), 129.6 (Ar-C\(_{CH}\)), 129.8 (Ar-C\(_{CH}\)), 130.1 (Ar-C\(_{CH}\)), 130.4 (Ar-C\(_{CH}\)), 138.2 (quat.Ar-CI), 138.3 (quat.Ar-C, ipso in phenyl ring) 140.3 (Ar-C\(_{CH}\)), 158.8 (C=O). \( m/z \) 380.21; \( C_{16}H_{14}NO_2I \) requires 379.0069

To a solution of \( R \)-(-)-4-isopropyl-2-oxazolidinone (109) (4.8 g, 37.2 mmol) in THF (80 mL) at ambient temperature under a nitrogen atmosphere was added potassium
butoxide (12% solution in THF, 50.0 g, 448 mmol) in one portion. After 30 min a solution of 2-iodobenzylbromide (73) (13.27 g, 44.8 mmol) in THF (20 mL) was added and monitored by HPLC for completion. On consumption of the starting material saturated potassium carbonate and TBME were added. The organic fraction was dried over magnesium sulphate and the solvent was removed under reduced pressure to yield the desired alkyalted oxazolidinone as a foam (110) (12.3 g, 35.7 mmol, 96%).

3-(2-iodo-benzyl)-4-benzyl-oxazolidin-2-one.
To a solution of $R$-(-)-4-benzyl-2-oxazolidinone (110) (5.00 g, 28.2 mmol) in THF (40 mL) at ambient temperature under a nitrogen atmosphere was added potassium butoxide (12% solution in THF, 32 mL, 256 mmol) in one portion. After 30 min a solution of 2-iodobenzylbromide (73) (7.61 g, 25.6 mmol) in THF (10 mL) was added and monitored by HPLC for completion. On consumption of the starting material saturated potassium carbonate and TBME were added. The organic fraction was dried over magnesium sulphate and the solvent was removed under reduced pressure to yield the desired alkylated oxazolidinone as a foam (111) (10.4 g, 26.6 mmol, 95%). $\nu_{\text{max}}$ (film) /cm$^{-1}$ 1750, 1418, 1237, 1081, 743, 701, 686. $[\alpha]_{D}^{20} = -26.8 \, ^\circ (c \; 1.09, \text{CHCl}_3)$. $\delta_{\text{H}}$ (400 MHz; CDCl$_3$) 2.64 (1 H, dd, $J$ 10.0 & 16.0 Hz, CH$_2$Ph), 3.17 (1 H, dd, $J$ 4.0 & 12.0 Hz, CH$_2$Ph), 3.82 – 3.88 (1 H, m, NCH$_2$Ph), 4.07 (1 H, dd, $J$ 4.0 & 8.0 Hz, OCH$_2$), 4.16 (1 H, t, $J$ 8.0 Hz, OCH$_2$), 4.44 (1 H, d, 16 Hz, NCH$_2$H), 4.81 (1 H, d, $J$ 16.0 Hz, NCH$_2$H), 7.00 – 7.05 (1 H, m, Ar-CH$_2$), 7.08 (2 H, d, $J$ 8.0 Hz, 2 x Ar-CH$_2$), 7.23 – 7.30 (3 H, m, 3 x Ar-CH$_2$), 7.37 (2 H, d, $J$ 4.0 Hz, Ar-CH$_2$), 7.87 (1 H, d, $J$ 8.0 Hz, Ar-CH$_2$). $\delta_{\text{C}}$ (100 MHz; CHCl$_3$) 38.4 (CH$_2$Ph), 50.9 (OCH$_2$), 56.0 (NCH$_2$), 66.8 (NCH$_2$H), 98.7 (quat.Ar-C, ipso in iodo phenyl ring), 127.7 (Ar-CH$_2$), 128.8 (Ar-CH$_2$), 128.9 (2 x Ar-CH$_2$), 129.1 (2 x Ar-CH$_2$), 129.5 (Ar-CH$_2$), 129.8 (Ar-CH$_2$), 135.4 (quat.Ar-Cl), 138.5 (quat.Ar-C in benzyl ring), 139.8 (Ar-CH$_2$), 158.2 (C=O). $m/z$ 394.03105; $C_{17}H_{17}NO_2I^{+}$ requires 394.03040.

General procedure for the addition of 3-(2-iodo-benzyl)-4-alkyl-oxazolidin-2-ones to acetylphenyl boronic acid using Suzuki methodology.

To a solution of the desired 3-(2-iodo-benzyl)-4-alkyl-oxazolidin-2-one (1 equiv.) in toluene (10 vol.) and ethanol (15 vol.), were added boronic acid (50) (1 equiv.) and saturated aqueous potassium carbonate solution (2M in water, 10 vol.). The reaction mixture was degassed with a nitrogen flow over 30 min. After adding the desired palladium catalyst (5%mol), the reaction mixture was degassed with a nitrogen flow over 15 min. The mixture was stirred at under reflux and under nitrogen atmosphere whilst monitoring by HPLC, once full consumption of the starting material was observed the
reaction was allowed to cool to ambient temperature. The solution was filtered through a plug of celite and toluene was removed under reduced pressure. To the resulting saturated aqueous phase TBME was added. After phase separation, the organic layer were washed with water and dried over MgSO₄. The solvents were removed under reduced pressure to afford the crude Suzuki biphenyl compound.

\]

Prepared according to the general procedure from the 3-(2-iodo-benzyl)-4-phenyl-oxazolidin-2-one (71) (0.46 g, 1.21 mmol), boronic acid (60) (0.20 g, 1.21 mmol) and \(\text{Pd(DPPF)}_4\) (70.0 mg, 0.06 mmol), to afford the crude biphenyl compound (70). The crude material was immediately carried forward into the next reaction.
3-(2'-acetyl-biphenyl-2-ylmethyl)-4-isopropyl-oxazolidin-2-one.

![Chemical structure](image)

Prepared according to the general procedure from the desired 3-(2-iodo-benzyl)-4-isopropyl-oxazolidin-2-one (110) (1.0 g, 2.90 mmol), boronic acid (60) (0.48 g, 2.90 mmol) and Pd(DPPF) (0.12 g, 0.15 mmol) to afford the crude biphenyl compound (112). The crude material was immediately carried forward into the next reaction.

3-(2'-acetyl-biphenyl-2-ylmethyl)-4-benzyl-oxazolidin-2-one.

![Chemical structure](image)
Prepared according to the general procedure from the desired 3-(2-iodo-benzyl)-4-benzyl-oxazolidin-2-one (111) (1.00 g, 2.90 mmol), boronic acid (60) (0.48 g, 2.9 mmol) and Pd(DPPF) (0.12 g, 0.15 mmol) to afford the crude biphenyl compound (113). The crude material was immediately carried forward into the next reaction.

General procedure for the deprotection of biphenyl oxazolidinones and the subsequent cyclisation in the generation tetracyclic compounds.

To a crude solution of the desired biphenyl oxazolidinone in ethanol (10 vol.) was added saturated aqueous NaOH (2M in water, 10 vol.). The reaction mixture was heated under reflux for 16 h then allowed to cool to ambient temperature. The organic solvent was removed under reduced pressure and the resulting residue was dissolved in TBME (10 vol.) and HCl (5M in water, 10 vol.). The reaction mixture was stirred for 30 min and the organic layer was separated, dried over magnesium sulphate and the solvent was removed under reduced pressure to yield the crude cyclised product. The desired compounds were isolated by flash chromatography on silica gel (ethyl acetate:heptane 1 – 5%).

4b-Methyl-7-phenyl-6,7-dihydro-4bH,8H-5-oxa-7a-aza-dibenzo(e,g) azulene.
Prepared according to the general procedure using a crude solution of 3-(2'-acetyl-biphenyl-2-ylmethyl)-4-phenyl-oxazolidin-2-one (70) to afford the desired tetracycle as one diastereoisomer isolated as a foam (62) (two steps; 0.049 g, 0.15 mmol, 12%).

$\nu_{\text{max}}$ (film) /cm$^{-1}$ 2963, 1449, 1260, 1153, 1038, 897, 802, 758, 740, 701. $[\alpha]^20_D$ = 25.1 ° (c 1.10, CHCl$_3$). $\delta_H$ (400 MHz; CDCl$_3$) 1.01 (3 H, s, NC(CH$_3$)$_2$O), 2.98 (1 H, d, J 10.8 Hz, NCHH), 3.47 (1 H, d, J 10.8 Hz, NCHH), 3.75 (1 H, dd, J 7.6 & 9.6 Hz, OCHH), 3.83 (1 H, dd, J 6.0 & 9.6 Hz, OCHH), 4.26 (1 H, dd, J 6.4 & 7.2 Hz, NCHPh), 7.12 (1 H, d, J 7.2 Hz, Biphenyl-CH), 7.19 – 7.24 (2 H, m, 2 x Ar-CH), 7.25 – 7.31 (3 H, m, 3 x Ar-CH), 7.33 – 7.41 (6 H, m, 4 x Biphenyl-CH & 2 x Ar-CH), 7.78 – 7.81 (1 H, m, Ar-CH). $\delta_C$ (100 MHz; CHCl$_3$) 29.4 (CH$_3$), 51.3 (OCH$_2$), 68.1 (CPh), 71.5 (NCH$_2$), 96.1 (NC(Me)O), 124.7 (Ar-CH), 126.4 (Ar-CH), 126.60 (Ar-CH), 126.63 (2 x Ar-CH), 126.80 (Ar-CH), 126.84 (Ar-CH), 126.9 (Ar-CH), 127.3 (Ar-CH), 127.6 (2 x Ar-CH), 127.9 (Ar-CH), 128.0 (Ar-CH), 134.0 (quat.Ar-C), 135.7 (quat.Ar-C), 137.9 (quat.Ar-C), 139.2 (quat.Ar-C), 140.9 (quat.Ar-C). m/z 327.16263 [+ 1.0 ppm]; C$_{23}$H$_{21}$NO requires 327.16231.

7-isopropyl-4b-methyl-6,7-dihydro-4bH,8H-5-oxa-7a-aza-dibenzo(e,g) azulene.
Prepared according to the general procedure using a crude solution of 3-(2'-acetyl-biphenyl-2-ylmethyl)-4-isopropyl-oxazolidin-2-one (112) to afford the desired tetracycle as one diastereoisomer, isolated as a foam (90) (two steps; 0.08 g, 0.29 mmol, 10%).

7-benzyl-4b-methyl-6,7-dihydro-4bH,8H-5-oxa-7a-aza-dibenzo(e,g) azulene.
Prepared according to the general procedure using a crude solution of 3-(2'-acetyl-biphenyl-2-ylmethyl)-4-isopropyl-oxazolidin-2-one (113) to afford the desired tetracycle as one diastereoisomer, isolated as a foam (94) (two step; 0.08 g, 0.23 mmol, 8%).

General procedure for the reductive amination using 2-iodobenzaldehyde and amino alcohols.

2-iodobenzaldehyde (1.1 equiv.) and the desired amino alcohol (1.0 equiv.) were dissolved in methanol (10 vol.) and agitated over 5 h. To the reaction mixture sodium cyanoborohydride (1.1 equiv.) was added and stirred at ambient temperature for 15 h. The reaction was quenched with ammonium chloride and the solvent was removed under reduced pressure. The remaining residue was dissolved in DCM and was separated from saturated brine and dried over magnesium sulphate. The crude oil was purified by column chromatography using a DCM/MeOH eluent (100:0 – 95:5) to yield the desired secondary amine.
**2S-(2-iodo-benzylamino)-propan-1-ol.**

\]

To a solution of \(R\)-phenylglycinol (57) (1.32 g, 9.60 mmol) in MeOH (25 mL) at 0 °C under a nitrogen atmosphere was added 2-iodobenzaldehyde (77) (2.20 g, 9.50 mmol). The reaction was allowed to warm to ambient temperature whilst being monitored by HPLC. When complete consumption of the starting materials was observed the crude reaction mixture was cooled to 0 °C and NaBH\(_4\) (0.66 g, 17.4 mmol) was added over 30 min. The reaction was then allowed to stir for 16 h at ambient temperature. The reaction mixture was then cooled to 0 °C and quenched with saturated NaHCO\(_3\) (10% in water, 30 mL). The organic solvent was removed under reduced pressure and dissolved with TBME. The organic fraction underwent saturated aqueous acid/base washing to isolate the pure amino alcohol as a colourless low melting solid (76) (2.77 g, 7.80 mmol, 81%). 

\([\alpha]^{20}_D +2.5 \, ^{{\circ}}\) (c 1.10, CHCl\(_3\)).

(2-Hydroxy-1-phenyl-ethyl)-(2-iodo-benzyl)-carbamic acid tert-butyl ester.

To 2-(2-iodo-benzylamino)-2-phenyl-ethanol (76) (0.38 g, 1.08 mmol) in THF (5 mL), di-tert-butyl dicarbonate (0.71 g, 3.24 mmol) and TEA (0.15 mL, 1.1 mmol) were added under a nitrogen atmosphere. The reaction was heated under reflux for 16 h at which the reaction was allowed to cool to ambient temperature. The organic solvent was removed under reduced pressure and re-dissolved in TBME, the crude reaction mixture then underwent saturated aqueous acid/base workup in an attempt to isolate the Boc-protected amido alcohol (118). No reaction was observed.
3-(2-Iodo-benzyl)-2,2-dimethyl-4-phenyl-oxazolidine.

To a solution of 2-(2-iodo-benzylamino)-2-phenyl-ethanol (76) (650 mg, 1.84 mmol) in toluene (10 mL) was added DMP (2.25 mL, 18.4 mmol) and p-TSA (70.0 mg, 0.37 mmol). The reaction was heated under reflux in Dean and Stark apparatus. The reaction was monitored by TLC and the azeotropic removal of solvents. The crude reaction mixture was separated from saturated brine (3 x 20 mL), dried over MgSO₄ and the solvent removed under reduced pressure. Purification via column chromatography using silica gel (washed with 4% TEA) and an ethylacetate/light petrol eluent (10%) yielded the desired acetal as a yellow low melting solid (75). (694 mg, 1.76 mmol, 96%).

General procedure for the addition of iodo-amino alcohols to acetylphenyl boronic acid using Suzuki methodology.

To a solution of the desired amino alcohol (1 equiv.) in toluene (10 vol.) and ethanol (1 vol.), were added boronic acid (1 equiv.) and saturated aqueous potassium carbonate solution (2M in water, 1 vol.). The reaction mixture was degassed with a nitrogen flow over 30 min. After adding the desired palladium catalyst (10%mol), the reaction mixture was then degassed over 15 min. The mixture was stirred at reflux under nitrogen atmosphere whilst monitoring by HPLC, once full consumption of the starting material was observed the reaction was allowed to cool to ambient temperature. The solution was filtered through a plug of celite and toluene was removed under reduced pressure. TBME was then added to the resulting saturated aqueous phase. After phase separation, the combined organic layers were washed with water and dried over MgSO4. The solvents were removed under reduced pressure to afford the crude Suzuki biphenyl compound.

General procedure for the oxidation of tertiary cyclic amines with N-bromosuccinimide.

To an ice-cooled solution of the desired tertiary cyclic amine (1 equiv.) in dichloromethane (5 vol.) was added N-bromosuccinimide (2 equiv.). The reaction mixture was removed from the ice bath and stirred for 20 min whilst monitoring by HPLC/TLC. Water (10 vol.) was added to the reaction mixture and the DCM layer was separated and dried over magnesium sulphate. The solvent was removed under reduced pressure to yield the desired tetracyclic iminium bromide salt.

4b,7-Dimethyl-6,7-dihydro-4bH-5-oxa-7a-azonia-dibenzo(e,g)azulene; bromide salt.

Prepared following the general procedure using 88 (0.21 g, 0.80 mmol) in dichloromethane (2 mL) and N-bromosuccinimide (0.29 g, 1.60 mmol) to yield the tetracyclic iminium bromide salt as a pair of diastereoisomers (82) (0.20 g, 0.59 mmol, 74%). ν_{max}(film)/cm$^{-1}$ 2965, 1704, 1652, 1558, 1259, 1184, 1102, 1017, 763, 615. \text{\begin{align*}
\text{\textbf{94}} & \quad \rightarrow \\
\text{\textbf{85}}
\end{align*}}
\]

Prepared following the general procedure using \textbf{94} (0.51 g, 1.60 mmol) in
dichloromethane (2 mL) was added N-bromosuccinimide (0.57 g, 3.20 mmol) to yield the desired tetracyclic iminium bromide salt (85) (0.62 g, 1.20 mmol, 75%). Having almost identical spectroscopic data to (84). $\nu_{\text{max}}$(film) /cm$^{-1}$ 3445, 2358, 1714, 1654, 1616, 1558, 1454, 1404, 1257, 1182, 1104, 744, 701, 668. $[\alpha]_{D}^{20}$ +15.0 ° (c 1.07, CHCl$_3$).

4b,7-Dimethyl-6-phenyl-6,7-dihydro-4bH-5-oxa-7a-azonia-dibenzo (e,g)azulene; bromide salt.

Prepared following the general procedure using 96 (0.11 g, 0.32 mmol) in dichloromethane (2 mL) was added N-bromosuccinimide (0.11 g, 0.64 mmol) to yield the desired tetracyclic iminium bromide salt. (86) (0.10 g, 0.24 mmol, 75%). $\nu_{\text{max}}$(film) /cm$^{-1}$ 3380, 3053, 2360, 1724, 1641, 1597, 1259, 1172, 908, 733, 703. $[\alpha]_{D}^{20}$ 10.1 ° (c 1.11, CHCl$_3$). $\delta_{\text{H}}$ (400 M Hz; CDCl$_3$) 0.98 (3 H, d, $J$ 6.8 Hz, CHCH$_3$), 1.32 (3 H, s, NC(CH$_3$)$_2$O), 3.80 – 3.86 (1 H, m, NCH(CH$_3$)$_2$), 4.99 – 4.98 (1 H, d, $J$ 4.8 Hz, CHPh), 6.66 – 6.70 (2 H, m, 2 x Ar-CH), 6.80 (2 H, t (dd), $J$ 7.2/7.6, 2 x Ar-CH), 7.26 – 7.31 (3 H, m, 3 x Ar-CH), 7.32 – 7.43 (2 H, m, 2 x Ar-CH), 7.49 – 7.52 (2 H, m, 2 x Ar-CH), 7.60 – 7.65 (1 H, m, Ar-CH), 7.80 – 7.82 (1 H, m, Ar-CH), $\delta_{C}$ (100 M Hz; CHCl$_3$) 16.9 (CHCH$_3$), 22.8 (NC(CH$_3$)$_2$O), 66.1 (NCH), 78.5 (CCH$_3$), 97.5 (quat.CCH$_3$), 121.1 (Ar-CH), 124.9 (Ar-CH), 126.1 (Ar-CH), 126.2 (Ar-CH), 127.3 (Ar-CH), 127.7 (Ar-CH), 127.9 (Ar-CH), 129.5 (Ar-CH), 130.8 (Ar-CH), 131.7 (Ar-CH), 135.0 (Ar-CH), 164.1
(N=C) (no signal for 5 x quaternary aromatic carbon atoms). m/z 340.17025 [+ 0.3 ppm]; C_{24}H_{22}NO^+ Br^- requires 340.17014.

**General procedure for the formation of racemic epoxides for ee determinations**

The alkene (1.0 equiv) was dissolved in dichloromethane (10 mL/g) and cooled to 0 °C. m-CPBA (2 equiv) was added as a solution in dichloromethane (10 mL/g). The reaction was allowed to attain ambient temperature temperature and stirred until complete consumption of the substrate was observed by TLC. The reaction was quenched with the addition of saturated aqueous NaHCO$_3$ (10 mL/g) and the layers separated. The organic layer was washed with saturated NaOH (1.0 M) (10 mL/g) and dried (MgSO$_4$). Solvents were removed under reduced pressure. The pure epoxide was obtained after column chromatography eluting with ethyl acetate/light petroleum (1:99).

**General procedure for catalytic asymmetric epoxidation of simple alkenes mediated by iminium salts using Oxone**

Oxone (2 equiv) was added to an ice cooled solution of Na$_2$CO$_3$, (4 equiv) in water (12 mL per 1.50 g of Na$_2$CO$_3$), the resulting foaming solution was left to stir for 5-10 min. The iminium salt (10 mol%) was then added as a solution in acetonitrile, (6 mL per 1.50 g of Na$_2$CO$_3$ used), followed by the alkene substrate (1 equiv) also as a solution in acetonitrile of the same volume as the solution of the catalyst. The mixture was stirred at 0 °C until the alkene substrate was completely consumed as observed by TLC. The reaction mixture was then dissolved with ice cooled diethyl ether (20 mL per 100 mg substrate) and was immediately followed by the addition of the same volume of water. The saturated aqueous phase was washed 4 times with diethyl ether and the organics
were combined, washed with saturated brine and dried over magnesium sulphate. Filtration and evaporation of the solvents gave a yellow/brown residue. The pure epoxide was obtained after column chromatography eluting with ethyl acetate/light petroleum (1:99).

**General procedure for catalytic asymmetric epoxidation of simple alkenes mediated by iminium salts using hydrogen peroxide and bicarbonate salts**

The bicarbonate salt (0.2 equiv) and the iminium salt catalyst (10 mol%) were dissolved in acetonitrile (1 mL) and cooled to −5 °C. To this solution the substrate alkene (1 equiv) and hydrogen peroxide (6 equiv) were added. The reaction was monitored by TLC until complete consumption of the substrate alkene was observed or after 24 h of reaction time has elapsed. The reaction was then quenched with saturated brine and extracted with diethyl ether. The ether layer was dried over MgSO₄ to give the crude epoxide.

**General procedure for catalytic asymmetric epoxidation of simple alkenes mediated by iminium salts using sodium hypochlorite and bicarbonate salts**

The bicarbonate salt (0.25 equiv) was dissolved in NaOCl (3 equiv) and cooled to 0 °C. In a separate vessel also cooled to 0 °C the iminium salt catalyst (10 mol%) and the substrate alkene (1 equiv) were dissolved in dichloromethane (1 mL). The dichloromethane solution was then added to the NaOCl solution. The reaction was monitored by TLC until complete consumption of the substrate alkene was observed or after 24 h of reaction time has elapsed. The reaction was then quenched with saturated brine and extracted with diethyl ether. The ether layer was dried over MgSO₄ to give the crude epoxide.
3.4 Chapter three references.

9 The m.p. and [α]D values of 38 recorded in the Aldrich catalogue are cited as authentic.
3.5 Appendices

3.5.2 Appendix A; X-Ray data reports

The crystallographic data for the structures presented in the text are given in this section. Crystallographic analyses were carried out at Loughborough University by Dr M. R. J. Elsegood

Crystal data and the structure refinement for 6-(2,2-Dimethyl-4-phenyl-[1,3]dioxan-5-yl)-5-methyl-5H-dibenzo [c, e]azepinium; bromide (44):

Identification code pcbp69
Chemical formula C_{53}H_{52}BCl_{4}NO_{2}
Formula weight 887.57
Temperature 150(2) K
Radiation, wavelength Mokα, 0.71073 Å
Crystal system, space group monoclinic, PS1
Unit cell parameters
\[ a = 11.0253(7) \text{ Å} \quad \alpha = 90^\circ \]
\[ b = 18.2597(11) \text{ Å} \quad \beta = 109.694(2) \ ^\circ \]
\[ c = 11.9748(2) \text{ Å} \quad \gamma = 90^\circ \]
Cell volume 2269.7(2) Å³
Z 2
Calculated density 1.299 g/cm³
Absorption coefficient \( \mu \) 0.304 mm⁻¹
F(000) 932
Crystal colour and size colourless, 0.70 x 0.49 x 0.30 mm³
Reflections for cell refinement 6011 (θ range 2.23 to 30.39°)
Data collection method Bruker APEX 2 CCD diffractometer
ω rotation with narrow frames
θ range for data collection 1.81 to 27.50°
Index ranges h – 14 to 14, k – 23 to 23, l – 15 to 15
Completeness to θ = 26.00° 99.9%
Intensity decay 0%
Reflections collected 22134
Independent reflection 10396 (R_{int} = 0.0247)
Reflections with F^2>2σ 9587
Absorption correction semi-empirical from equivalents
Min. and max. transmission 0.816 and 0.914
Structure solution direct methods
Refinement method Full-matrix least squares on F^2
Weighting parameters a, b 0.1599, 1.0002
Data/restraints/parameters 10396/1/553
Final R indices [F^2>2σ] R1 = 0.0712, wR2 = 0.2110
R indices (all data) R1 = 0.0763, wR2 = 0.2197
Goodness-of-fit on F2 1.073
Absolute structure parameter 0.01(9), well determined
Largest and mean shift/su 0.001 and 0.000
Largest diff. peak and hole 0.812 and –1.054 e Å^-3

Crystal data and the structure refinement for 4b-Methyl-7-phenyl-6,7-dihydro-4bH-5-oxa-7a-azonia-dibenzo[e,g] azulene. (80):
